1 Time-dependent Schrödinger equation and evolution operators

We aim to find a solution for the time-dependent Schrödinger equation.

$$i \frac{\partial}{\partial t} |\Psi(t)\rangle = \hat{H}(t) |\Psi(t)\rangle$$

For time-independent Hamiltonian $\hat{H}(t) = \hat{H}(t_0)$ (for all t), we have

$$|\Psi(t)\rangle = e^{-i\hat{H}(t_0)(t-t_0)} |\Psi(t_0)\rangle$$

What we are actually looking for, is the evolution operator.

- The evolution operator $\hat{U}(t, t_0)$ is defined as:

$$|\Psi(t)\rangle = \hat{U}(t, t_0) |\Psi(t_0)\rangle$$

where $\hat{U}(t, t_0)$ is unitary.

- If $t > t_0$, \hat{H} is piecewise constant, i.e. for $t_0 < t_1 < \dots < t_n < t_{n+1} = t$

$$\hat{H}(\tau) = \hat{H}(t_p) \text{ for } t_p < \tau < t_{p+1},$$

Then we have

$$\begin{aligned} |\Psi(t)\rangle &= e^{-i\hat{H}(t_n)(t-t_n)} |\Psi(t_n)\rangle = e^{-i\hat{H}(t_n)(t-t_n)} e^{-i\hat{H}(t_{n-1})(t_n-t_{n-1})} |\Psi(t_{n-1})\rangle \\ &= e^{-i\hat{H}(t_n)(t-t_n)} e^{-i\hat{H}(t_{n-1})(t_n-t_{n-1})} \dots e^{-i\hat{H}(t_0)(t_1-t_0)} |\Psi(t_0)\rangle \end{aligned}$$

For simplicity, let's assume for now all $t_{p+1} - t_p = \Delta t$.

- Now we are ready to introduce time-ordering operator \hat{T} . \hat{T} acts on the product of m Hamiltonians of different time in the following way:

$$\hat{T} \left(\hat{H}(t_1) \dots \hat{H}(t_m) \right) = \hat{H}(t_{P(1)}) \dots \hat{H}(t_{P(m)})$$

where t_1, \dots, t_m are rearranged in the increasing order: $t_{P(1)} \geq \dots \geq t_{P(m)}$.

- Why do we introduce the time-ordering operator? It is because we want to write

$$e^{-i\hat{H}(t_n)\Delta t} e^{-i\hat{H}(t_{n-1})\Delta t} \dots e^{-i\hat{H}(t_0)\Delta t}$$

in a more compact way. However, $\hat{H}(t_i)$ and $\hat{H}(t_j)$ probably doesn't commute, therefore

$$e^{-i\hat{H}(t_n)\Delta t} e^{-i\hat{H}(t_{n-1})\Delta t} \dots e^{-i\hat{H}(t_0)\Delta t} \neq e^{-i\Delta t(\hat{H}(t_n)+\hat{H}(t_{n-1})+\dots+\hat{H}(t_0))}$$

But with time ordering operators, we actually have:

$$e^{-i\hat{H}(t_n)\Delta t} e^{-i\hat{H}(t_{n-1})\Delta t} \dots e^{-i\hat{H}(t_0)\Delta t} = \hat{T} \left(e^{-i\Delta t(\hat{H}(t_n)+\hat{H}(t_{n-1})+\dots+\hat{H}(t_0))} \right)$$

You can verify this through Taylor expansion, but another straightforward way to see this is that under \hat{T} , $\hat{H}(t_i)$ and $\hat{H}(t_j)$ does commute.

- In one word, for piecewise constant Hamiltonian, we have

$$|\Psi(t)\rangle = \hat{T} \left(e^{-i\Delta t(\sum_p \hat{H}(t_p))} \right) |\Psi(t_0)\rangle$$

- In the spirit of Riemann integral, for general time-dependent Hamiltonian, we should have

$$\begin{aligned} |\Psi(t)\rangle &= \lim_{\Delta t \rightarrow 0} \hat{T} \left(e^{-i\Delta t(\sum_p \hat{H}(t_p))} \right) |\Psi(t_0)\rangle \\ &= \hat{T} \left(e^{-i \int_{t_0}^t d\tau \hat{H}(\tau)} \right) |\Psi(t_0)\rangle \end{aligned}$$

The time evolution operator is, for $t > t_0$

$$\hat{U}(t, t_0) = \hat{T} \left(e^{-i \int_{t_0}^t d\tau \hat{H}(\tau)} \right)$$

- The time evolution operator satisfies the time-dependent Schrödinger equation itself:

$$i \frac{\partial}{\partial t} \hat{U}(t, t_0) = \hat{H}(t) \hat{U}(t, t_0), \quad \hat{U}(t_0, t_0) = \mathbf{1}$$

From this we can also derive the formalism for time evolution operator above. We have

$$\hat{U}(t, t_0) = \mathbf{1} - i \int_{t_0}^t dt_1 \hat{H}(t_1) \hat{U}(t_1, t_0)$$

We can substitute \hat{U} back into itself again and again, and get:

$$\begin{aligned} \hat{U}(t, t_0) &= \mathbf{1} - i \int_{t_0}^t dt_1 \hat{H}(t_1) + (-i)^2 \int_{t_0}^t dt_1 \int_{t_0}^{t_1} dt_2 \hat{H}(t_1) \hat{H}(t_2) \hat{U}(t_2, t_0) \\ &= \sum_{k=0}^{\infty} \frac{(-i)^k}{k!} \int_{t_0}^t dt_1 \int_{t_0}^{t_1} dt_2 \dots \int_{t_0}^{t_{k-1}} dt_k \hat{H}(t_1) \hat{H}(t_2) \dots \hat{H}(t_k) \end{aligned}$$

Note that

$$\int_{t_0}^t dt_1 \int_{t_0}^{t_1} dt_2 \dots \int_{t_0}^{t_{k-1}} dt_k \hat{H}(t_1) \hat{H}(t_2) \dots \hat{H}(t_k) = \frac{1}{k!} \int_{t_0}^t dt_1 \int_{t_0}^{t_1} dt_2 \dots \int_{t_0}^{t_{k-1}} dt_k \hat{T} \left(\hat{H}(t_1) \hat{H}(t_2) \dots \hat{H}(t_k) \right)$$

Therefore

$$\begin{aligned} \hat{U}(t, t_0) &= \sum_{k=0}^{\infty} \frac{(-i)^k}{k!} \int_{t_0}^t dt_1 \int_{t_0}^{t_1} dt_2 \dots \int_{t_0}^{t_{k-1}} dt_k \hat{T} \left(\hat{H}(t_1) \hat{H}(t_2) \dots \hat{H}(t_k) \right) \\ &= \hat{T} \left(e^{-i \int_{t_0}^t d\tau \hat{H}(\tau)} \right) \end{aligned}$$

- Similarly, we can prove, for $t < t_0$, we have

$$\hat{U}(t, t_0) = \bar{T} \left(e^{i \int_t^{t_0} d\tau \hat{H}(\tau)} \right)$$

where \bar{T} is the anti-chronological time ordering operator, which reorders the operators with time increasing from the left to the right.

2 Operators in the Heisenberg picture

- With the evolution operator $\hat{U}(t, t_0)$,

$$|\Psi(t)\rangle = \hat{U}(t, t_0)|\Psi_0\rangle$$

- For operator $\hat{O}(t)$, the observation expectation is

$$\langle \Psi(t) | \hat{O}(t) | \Psi(t) \rangle = \langle \Psi_0 | \hat{U}(t_0, t) \hat{O}(t) \hat{U}(t, t_0) | \Psi_0 \rangle$$

Therefore we define the following operator \hat{O}_H , which is called operator in the Heisenberg representation:

$$\hat{O}_H(t) = \hat{U}(t_0, t) \hat{O}(t) \hat{U}(t, t_0)$$

- For example, for density operator $\hat{n}(\mathbf{x}) = \hat{\psi}^\dagger(\mathbf{x}) \hat{\psi}(\mathbf{x})$, we have $\hat{n}_H(\mathbf{x}, t)$ as followed:

$$\begin{aligned} \hat{n}_H(\mathbf{x}, t) &= \hat{U}(t_0, t) \hat{\psi}^\dagger(\mathbf{x}) \hat{\psi}(\mathbf{x}) \hat{U}(t, t_0) = \hat{U}(t_0, t) \hat{\psi}^\dagger(\mathbf{x}) \hat{U}(t, t_0) \hat{U}(t_0, t) \hat{\psi}(\mathbf{x}) \hat{U}(t, t_0) \\ &= \hat{\psi}_H^\dagger(\mathbf{x}) \hat{\psi}_H(\mathbf{x}) \end{aligned}$$

- Basic property: if $C = AB$, then $C_H = A_H B_H$; $[A_H, B_H] = ([A, B])_H$.
- (Anti-)commutation relation:

$$[\hat{\psi}(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t)] = \delta(\mathbf{x} - \mathbf{x}')$$

- With some calculation, we have the equation of motion:

$$i \frac{\partial}{\partial t} \hat{O}_H(t) = [\hat{O}_H(t), \hat{H}_H(t)]_- + i \left(\frac{\partial \hat{O}}{\partial t} \right)_H(t)$$

- We consider the following Hamiltonian $\hat{H}(t)$

$$\begin{aligned} \hat{H}(t) &= \int d\mathbf{x} \hat{\psi}^\dagger(\mathbf{x}) \hat{h}(\mathbf{x}, t) \hat{\psi}(\mathbf{x}) + \frac{1}{2} \int d\mathbf{x} d\mathbf{x}' \hat{\psi}^\dagger(\mathbf{x}) \hat{\psi}^\dagger(\mathbf{x}') v(\mathbf{x}, \mathbf{x}') \hat{\psi}(\mathbf{x}') \hat{\psi}(\mathbf{x}) \\ &= H_0 + H_{\text{int}} \end{aligned}$$

- With this Hamiltonian, we can figure out the equation of motion for field operator. We need to calculate:

$$\begin{aligned}
\left[\hat{\psi}(\mathbf{x}), \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') \right] &= \hat{\psi}(\mathbf{x}) \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') - \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') \hat{\psi}(\mathbf{x}) \\
&= \hat{\psi}(\mathbf{x}) \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') \mp \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') \hat{\psi}(\mathbf{x}) = \hat{\psi}(\mathbf{x}') \delta(\mathbf{x} - \mathbf{x}') \\
\left[\hat{\psi}^\dagger(\mathbf{x}), \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') \right] &= \hat{\psi}^\dagger(\mathbf{x}) \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') - \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}) \\
&= \pm \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}) \hat{\psi}(\mathbf{x}') - \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}) = -\hat{\psi}^\dagger(\mathbf{x}') \delta(\mathbf{x}' - \mathbf{x}) \\
\left[\hat{\psi}(\mathbf{x}), \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'') \hat{\psi}(\mathbf{x}'') \hat{\psi}(\mathbf{x}') \right] &= \hat{\psi}(\mathbf{x}) \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'') \hat{\psi}(\mathbf{x}'') \hat{\psi}(\mathbf{x}') - \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'') \hat{\psi}(\mathbf{x}'') \hat{\psi}(\mathbf{x}') \hat{\psi}(\mathbf{x}) \\
&= \hat{\psi}(\mathbf{x}) \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'') \hat{\psi}(\mathbf{x}'') \hat{\psi}(\mathbf{x}') - \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'') \hat{\psi}(\mathbf{x}) \hat{\psi}(\mathbf{x}'') \hat{\psi}(\mathbf{x}') \\
&= \left(\hat{\psi}(\mathbf{x}) \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'') - \hat{\psi}^\dagger(\mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'') \hat{\psi}(\mathbf{x}) \right) \hat{\psi}(\mathbf{x}'') \hat{\psi}(\mathbf{x}') \\
&= \left([\hat{\psi}(\mathbf{x}), \hat{\psi}^\dagger(\mathbf{x}')]_{\mp} \hat{\psi}^\dagger(\mathbf{x}'') \pm \hat{\psi}^\dagger(\mathbf{x}') [\hat{\psi}(\mathbf{x}), \hat{\psi}^\dagger(\mathbf{x}'')]_{\mp} \right) \hat{\psi}(\mathbf{x}'') \hat{\psi}(\mathbf{x}') \\
&= \left(\delta(\mathbf{x} - \mathbf{x}') \hat{\psi}^\dagger(\mathbf{x}'') \pm \hat{\psi}^\dagger(\mathbf{x}') \delta(\mathbf{x} - \mathbf{x}'') \right) \hat{\psi}(\mathbf{x}'') \hat{\psi}(\mathbf{x}')
\end{aligned}$$

Then we have:

$$\begin{aligned}
i \frac{\partial}{\partial t} \hat{\psi}_H(\mathbf{x}, t) &= \hat{h}(\mathbf{x}, t) \hat{\psi}_H(\mathbf{x}, t) + \int d\mathbf{x}' v(\mathbf{x}, \mathbf{x}') \hat{\psi}_H^\dagger(\mathbf{x}', t) \hat{\psi}_H(\mathbf{x}', t) \hat{\psi}_H(\mathbf{x}, t) \\
i \frac{\partial}{\partial t} \hat{\psi}_H^\dagger(\mathbf{x}, t) &= -\hat{h}(\mathbf{x}, t) \hat{\psi}_H^\dagger(\mathbf{x}, t) - \int d\mathbf{x}' v(\mathbf{x}, \mathbf{x}') \hat{\psi}_H^\dagger(\mathbf{x}, t) \hat{\psi}_H^\dagger(\mathbf{x}', t) \hat{\psi}_H(\mathbf{x}', t)
\end{aligned}$$

3 Schwinger-Keldysh contour

We start by considering how to calculate the time-dependent quantum average of an operator $\hat{O}(t)$. Let $|\Psi(t_0)\rangle = |\Psi_0\rangle$, for $t > t_0$, we have:

$$\langle \hat{O} \rangle(t) = \langle \Psi(t) | \hat{O}(t) | \Psi(t) \rangle = \langle \Psi_0 | \hat{U}(t_0, t) | \hat{O}(t) | \hat{U}(t, t_0) | \Psi_0 \rangle$$

With the formula derived in the previous section, we have:

$$\langle \hat{O} \rangle(t) = \left\langle \Psi_0 \left| \bar{T} \left(e^{-i \int_{t_0}^t d\tau \hat{H}(\tau)} \right) \right| \hat{O}(t) \right| T \left(e^{-i \int_{t_0}^t d\tau \hat{H}(\tau)} \right) \left| \Psi_0 \right\rangle$$

If we do Taylor expansions, our job will be reduced to evaluate the integrals of the following forms:

$$\bar{T} \left(\hat{H}(t_1) \cdots \hat{H}(t_n) \right) \hat{O}(t) \hat{T} \left(\hat{H}(t'_1) \cdots \hat{H}(t'_m) \right)$$

in which t_i, t'_i is between t_0 and t .

There are two separate time-ordering operators in this formula. We want to use a general time-ordering operator \mathcal{T} to simplify this formulation.

- We start by defining an oriented contour:

$$\gamma := (t_0, t) \oplus (t, t_0) = \gamma_- \oplus \gamma_+$$

Figure 1: The oriented contour $\gamma = \gamma_- \oplus \gamma_+$

- γ_- is the forward branch. γ_+ is the backward branch.
- For a time $z \in \gamma$, if it's time t and it's on forward branch γ_- , we call it $z = t_-$, meaning that it's time t and it's used on the forward branch.
- For a time $z \in \gamma$, if it's time t and it's on backward branch γ_+ , we call it $z = t_+$, meaning that it's time t and it's used on the backward branch.
- We have

$$\hat{H}(t_+) = \hat{H}(t_-) = \hat{H}(t), \quad \hat{O}(t_+) = \hat{O}(t_-) = \hat{O}(t)$$

- The oriented contour defines an ordering of time. For $t_-^{(1)}, t_-^{(2)}, t_+^{(3)}, t_+^{(4)}$, we have:

$$t_{0+} > t_+^{(3)} > t_+^{(4)} > t_+ = t_- > t_-^{(2)} > t_-^{(1)} > t_{0-}$$

- With this well-defined ordering, we can define a generic time-ordering operator \mathcal{T} , called the contour ordering operator, which operates as followed: for $z_1, \dots, z_m \in \gamma$

$$\mathcal{T} \left(\hat{A}_1(z_1) \cdots \hat{A}_m(z_m) \right) = \hat{A}_{P(1)}(z_{P(1)}) \cdots \hat{A}_{P(m)}(z_{P(m)})$$

where $z_{P(1)} > \cdots > z_{P(m)}$, which is the ordering defined by the contour.

- Therefore, we have

$$\begin{aligned} & \bar{T} \left(\hat{H}(t_1) \cdots \hat{H}(t_n) \right) \hat{O}(t) \hat{T} \left(\hat{H}(t'_1) \cdots \hat{H}(t'_m) \right) \\ &= \mathcal{T} \left(\hat{H}(t_{1+}) \cdots \hat{H}(t_{n+}) \hat{O}(t_{\pm}) \hat{H}(t'_{1-}) \cdots \hat{H}(t'_{m-}) \right) \end{aligned}$$

- Now we are ready to rewrite the quantum average in contour integral. We have

$$\begin{aligned} & \int_t^{t_0} dt_1 \cdots \int_t^{t_0} dt_n \int_{t_0}^t dt'_1 \cdots \int_{t_0}^t dt'_m \bar{T} \left(\hat{H}(t_1) \cdots \hat{H}(t_n) \right) \hat{O}(t) \hat{T} \left(\hat{H}(t'_1) \cdots \hat{H}(t'_m) \right) \\ &= \int_{\gamma_+} dz_1 \cdots \int_{\gamma_+} dz_n \int_{\gamma_-} dz'_1 \cdots \int_{\gamma_-} dz'_m \mathcal{T} \left(\hat{H}(z_1) \cdots \hat{H}(z_n) \hat{O}(t_{\pm}) \hat{H}(z'_1) \cdots \hat{H}(z'_m) \right) \end{aligned}$$

- Then, the original quantum average could be written in the form of

$$\langle O \rangle(t) = \left\langle \Psi_0 \left| \mathcal{T} \left(e^{-i \int_{\gamma_+} dz \hat{H}(z)} \hat{O}(t_{\pm}) e^{-i \int_{\gamma_-} dz \hat{H}(z)} \right) \right| \Psi_0 \right\rangle$$

Note that all these operators in \mathcal{T} commutes, therefore we have

$$\langle O \rangle(t) = \left\langle \Psi_0 \left| \mathcal{T} \left(e^{-i \int_{\gamma} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) \right| \Psi_0 \right\rangle$$

In fact, there is more that we can do. As γ here actually rely on t , we can replace γ with a new contour that doesn't rely on t . Let our new $\tilde{\gamma}$ be

$$\tilde{\gamma} = (t_0, +\infty) \oplus (+\infty, t_0)$$

Then, with this γ , we have

$$\mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} O(t_-) \right) = \hat{U}(t_0, \infty) \hat{U}(\infty, t) \hat{O}(t) \hat{U}(t, t_0) = \hat{U}(t_0, t) \hat{O}(t) \hat{U}(t, t_0)$$

$$\mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} O(t_+) \right) = \hat{U}(t_0, t) \hat{O}(t) \hat{U}(t, \infty) \hat{U}(\infty, t_0) = \hat{U}(t_0, t) \hat{O}(t) \hat{U}(t, t_0)$$

Then, we have the final result, which is very elegant:

$$\langle O \rangle(t) = \left\langle \Psi_0 \left| \mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) \right| \Psi_0 \right\rangle$$

This $\tilde{\gamma}$ is referred to as Schwinger-Keldysh contour.

4 Konstantinov-Perel contour for ensemble averages

Now we turn to the ensemble averages, which is probably a mixed state, rather than a pure state in the previous section.

The setup of the problem is as followed:

- For Hamiltonian \hat{H}^M , (M is credited to Matsubara), let's assume its eigenpairs being $(E_k^M, |\Psi_k\rangle)$. The Hamiltonian could be reconstructed as

$$\hat{H} = \sum_k E_k^M |\Psi_k\rangle \langle \Psi_k|$$

- The density matrix, $\hat{\rho}$, is defined as

$$\hat{\rho} = \frac{1}{Z} e^{-\beta H} = \frac{1}{Z} \sum_k e^{-\beta E_k^M} |\Psi_k\rangle \langle \Psi_k|$$

where Z is set to be $\text{Tr}(e^{-\beta H}) = \sum_k e^{-\beta E_k^M}$ to make sure $\text{Tr}(\hat{\rho}) = 1$. Here β is

$$\beta = \frac{1}{k_B T}$$

- With density matrix $\hat{\rho}$, the ensemble average of an operator \hat{O} is

$$\langle \hat{O} \rangle = \text{Tr}(\hat{\rho} \hat{O})$$

- For an ensemble in thermodynamic equilibrium, described by temperature T and chemical potential μ , the Hamiltonian \hat{H}^M is

$$\hat{H}^M = \hat{H} - \mu \hat{N}$$

- In the previous section, we have the result

$$\hat{U}(t_0, t) \hat{O}(t) \hat{U}(t, t_0) = \mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right)$$

Then the ensemble average is

$$\begin{aligned} \langle \hat{O} \rangle(t) &= \left\langle \text{Tr}(\hat{U}(t_0, t) \hat{O}(t) \hat{U}(t, t_0)) \right\rangle = \text{Tr} \left(\hat{\rho} \mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) \right) \\ &= \frac{\text{Tr} \left(e^{-\beta \hat{H}^M} \mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) \right)}{\text{Tr} \left(e^{-\beta \hat{H}^M} \right)} \end{aligned}$$

This is partly written using the contour formalism.

- In fact, we can try to express the above formula only using contour integrals. Let z_a, z_b be the points in complex plane, such that

$$z_b - z_a = -i\beta$$

- Let γ^M be (any of) the contour starting from z_a ending in z_b , then we have

$$e^{-\beta \hat{H}^M} = e^{-i \int_{\gamma^M} dz \hat{H}^M}$$

For $z \in \gamma^M$, we can also define the value of Hamiltonian $H^M(z)$ on γ^M . We just choose $H^M(z) = H(t_0)$.

- We also have

$$\mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \right) = \hat{U}(t_0, \infty) \hat{U}(\infty, t_0) = \mathbf{1}$$

- Then, combined those two equations, we have:

$$\langle \hat{O} \rangle(t) = \frac{\text{Tr} \left(e^{-i \int_{\gamma^M} dz \hat{H}^M} \mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) \right)}{\text{Tr} \left(e^{-i \int_{\gamma^M} dz \hat{H}^M} \mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \right) \right)}$$

- In this case, $\hat{H}(z) = \hat{H}^M$ for all z .
- We haven't decided what is z_a, z_b and γ^M yet, just saying that $z_b - z_a = -i\beta$. As shown in figure 2, we do have different choices.

Using γ^M and the original γ_-, γ_+ , we can construct new oriented contour γ :

$$\gamma = \gamma_- \oplus \gamma_+ \oplus \gamma^M = \tilde{\gamma} \oplus \gamma^M$$

and define the ordering using this oriented contour γ .

Figure 2: Different choices of z_a, z_b

- Now, for example, for the left choice of figure 2, we have:

$$\begin{aligned} \text{Tr} \left(e^{-i \int_{\gamma^M} dz \hat{H}^M} \mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) \right) &= \text{Tr} \left(e^{-i \int_{z_a}^{t_0-} dz \hat{H}^M} \mathcal{T} \left(e^{-i \int_{\tilde{\gamma}} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) e^{-i \int_{t_0+}^{z_b} dz \hat{H}^M} \right) \\ &= \text{Tr} \left(\mathcal{T} \left(e^{-i \int_{\tilde{\gamma} \oplus \gamma^M} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) \right) \end{aligned}$$

- In general, we have

$$\langle \hat{O} \rangle(t) = \frac{\text{Tr} \left(\mathcal{T} \left(e^{-i \int_{\tilde{\gamma} \oplus \gamma^M} dz \hat{H}(z)} \hat{O}(t_{\pm}) \right) \right)}{\text{Tr} \left(\mathcal{T} \left(e^{-i \int_{\tilde{\gamma} \oplus \gamma^M} dz \hat{H}(z)} \right) \right)}$$

In fact, this value could also be generalized to any $z \in \gamma$, not only real-time t , but also imaginary time z on γ^M :

$$\langle \hat{O} \rangle(z) = \frac{\text{Tr} \left(\mathcal{T} \left(e^{-i \int_{\tilde{\gamma} \oplus \gamma^M} dz \hat{H}(z)} \hat{O}(z) \right) \right)}{\text{Tr} \left(\mathcal{T} \left(e^{-i \int_{\tilde{\gamma} \oplus \gamma^M} dz \hat{H}(z)} \right) \right)}$$

5 Equation of motion on the contour

- As an analogy to the evolution operator for quantum system, we define the following evolution operator on the contour:

$$\hat{U}(z_2, z_1) = \begin{cases} \mathcal{T} \left(e^{-i \int_{z_1}^{z_2} dz \hat{H}(z)} \right), & z_2 \text{ later than } z_1 \\ \bar{\mathcal{T}} \left(e^{+i \int_{z_2}^{z_1} dz \hat{H}(z)} \right), & z_1 \text{ later than } z_2 \end{cases}$$

The integral is taken along the contour.

- This evolution operator has the following property:

$$\hat{U}(z, z) = \mathbf{1}, \quad \hat{U}(z_3, z_2) \hat{U}(z_2, z_1) = \hat{U}(z_3, z_1)$$

- Now let's calculate the derivative. If z is later than z_0 , we have

$$i \frac{\partial}{\partial z} \hat{U}(z, z_0) = \mathcal{T} \left(i \frac{\partial}{\partial z} e^{-i \int_{z_0}^z d\bar{z} \hat{H}(\bar{z})} \right) = \mathcal{T} \left(\hat{H}(z) e^{-i \int_{z_0}^z d\bar{z} \hat{H}(\bar{z})} \right) = \hat{H}(z) \hat{U}(z, z_0)$$

$$i \frac{\partial}{\partial z} \hat{U}(z_0, z) = \bar{\mathcal{T}} \left(i \frac{\partial}{\partial z} e^{i \int_{z_0}^z d\bar{z} \hat{H}(\bar{z})} \right) = -\bar{\mathcal{T}} \left(\hat{H}(z) e^{i \int_{z_0}^z d\bar{z} \hat{H}(\bar{z})} \right) = -\hat{U}(z_0, z) \hat{H}(z)$$

- We have the following relation between evolution operator on contour $\hat{U}(z_2, z_1)$ and the ordinary evolution operator $\hat{U}(t_2, t_1)$:

$$\hat{U}(t_2, t_1) = \hat{U}(t_{2-}, t_{1-}) = \hat{U}(t_{2+}, t_{1+})$$

- Let's denote by z_i the initial point of the contour, by z_f the final point of the contour. Then:

$$O(z) = \frac{\text{Tr} \left(\hat{U}(z_f, z_i) \hat{U}(z_i, z) \hat{O}(z) \hat{U}(z, z_i) \right)}{\text{Tr} \left(\hat{U}(z_f, z_i) \right)}$$

- It seems natural to define the contour Heisenberg picture:

$$\hat{O}_H(z) = \hat{U}(z_i, z) \hat{O}(z) \hat{U}(z, z_i)$$

- If z lies on the horizontal branches, the contour Heisenberg picture and the standard Heisenberg picture is:

$$\hat{O}_H(t_1) = \hat{O}_H(t_2) = \hat{O}_H(t)$$

- Equation of motion:

$$\begin{aligned} i \frac{\partial}{\partial z} \hat{O}_H(z) &= \hat{U}(z_i, z) [\hat{O}(z), \hat{H}(z)] \hat{U}(z, z_i) + i \left(\frac{\partial \hat{O}}{\partial z} \right)_H(z) \\ &= [\hat{O}_H(z), \hat{H}_H(z)] + i \left(\frac{\partial \hat{O}}{\partial z} \right)_H(z) \end{aligned}$$

- For example, field operators $\hat{\psi}_H(\mathbf{x}, t)$, $\hat{\psi}_H^\dagger(\mathbf{x}, t)$ also have the contour analog $\hat{\psi}_H(\mathbf{x}, z)$, $\hat{\psi}_H^\dagger(\mathbf{x}, z)$.
- For $\hat{\psi}(\mathbf{x}, z)$, $\hat{\psi}^\dagger(\mathbf{x}, z)$, we only need to specify the definition on the γ^M :

$$\hat{\psi}(\mathbf{x}, z \in \gamma^M) = \hat{\psi}(\mathbf{x}), \quad \hat{\psi}^\dagger(\mathbf{x}, z \in \gamma^M) = \hat{\psi}^\dagger(\mathbf{x})$$

In other words, the field operators are constant over the entire contour. Generally, we only consider \hat{H}^M of the form:

$$\begin{aligned} \hat{H}^M &= \int d\mathbf{x} \hat{\psi}^\dagger(\mathbf{x}) \hat{h}(\mathbf{x}, z) \hat{\psi}(\mathbf{x}) + \frac{1}{2} \int d\mathbf{x} d\mathbf{x}' \hat{\psi}^\dagger(\mathbf{x}) \hat{\psi}^\dagger(\mathbf{x}') v(\mathbf{x}, \mathbf{x}') \hat{\psi}(\mathbf{x}') \hat{\psi}(\mathbf{x}) \\ &= \hat{H}_0^M + \hat{H}_{\text{int}}^M \end{aligned}$$

- Neglecting spins, we have the following equation of motion:

$$i \frac{\partial}{\partial z} \hat{\psi}_H(\mathbf{x}, z) = \hat{h}(\mathbf{x}, z) \hat{\psi}_H(\mathbf{x}, z) + \int d\mathbf{x}' v(\mathbf{x}, \mathbf{x}', z) \hat{\psi}_H^\dagger(\mathbf{x}', z) \hat{\psi}_H(\mathbf{x}', z) \hat{\psi}_H(\mathbf{x}, z)$$

$$i \frac{\partial}{\partial z} \hat{\psi}_H^\dagger(\mathbf{x}, z) = -\hat{h}(\mathbf{x}, z) \hat{\psi}_H^\dagger(\mathbf{x}, z) - \int d\mathbf{x}' v(\mathbf{x}, \mathbf{x}', z) \hat{\psi}_H^\dagger(\mathbf{x}, z) \hat{\psi}_H^\dagger(\mathbf{x}', z) \hat{\psi}_H(\mathbf{x}', z)$$

6 Operators correlators on the contour

- It has been shown that, in order to calculate $\langle O \rangle(t)$, after taylor expansion, the quantity that we are concerned about are traces of the following forms:

$$\hat{k}(z_1, \dots, z_n) = \mathcal{T} \left(\hat{O}_1(z_1) \cdots \hat{O}_n(z_n) \right)$$

These are what we call operator correlators.

- Define $\theta(z_1, z_2)$:

$$\theta(z_1, z_2) = \begin{cases} 1 & z_1 > z_2 \\ 0 & z_1 \leq z_2 \end{cases}$$

its derivative is the delta function:

$$\frac{d}{dz_1} \theta(z_1, z_2) = \delta(z_1, z_2), \quad \frac{d}{dz_2} \theta(z_1, z_2) = -\delta(z_1, z_2)$$

- For two operator case $\mathcal{T} \left(\hat{O}_1(z_1) \hat{O}_2(z_2) \right)$, we have:

$$\mathcal{T} \left(\hat{O}_1(z_1) \hat{O}_2(z_2) \right) = \theta(z_1, z_2) \hat{O}_1(z_1) \hat{O}_2(z_2) + \theta(z_2, z_1) \hat{O}_2(z_2) \hat{O}_1(z_1)$$

Then the derivative is:

$$\frac{d}{dz_1} \mathcal{T} \left(\hat{O}_1(z_1) \hat{O}_2(z_2) \right) = \delta(z_1, z_2) \left[\hat{O}_1(z_1), \hat{O}_2(z_2) \right] + \mathcal{T} \left(\left(\frac{d}{dz_1} \hat{O}_1(z_1) \right) \hat{O}_2(z_2) \right)$$

- The commutator is actual for bosons. For fermions, we prefer anti-commutators. Therefore, if \hat{O}_1, \hat{O}_2 are fermionic operators, we modify our definition of time-ordering operator:

$$\mathcal{T} \left(\hat{O}_1(z_1) \hat{O}_2(z_2) \right) = \theta(z_1, z_2) \hat{O}_1(z_1) \hat{O}_2(z_2) - \theta(z_2, z_1) \hat{O}_2(z_2) \hat{O}_1(z_1)$$

Then, the derivative is:

$$\frac{d}{dz_1} \mathcal{T} \left(\hat{O}_1(z_1) \hat{O}_2(z_2) \right) = \delta(z_1, z_2) \left\{ \hat{O}_1(z_1), \hat{O}_2(z_2) \right\} + \mathcal{T} \left(\left(\frac{d}{dz_1} \hat{O}_1(z_1) \right) \hat{O}_2(z_2) \right)$$

- Generally, for n operators, we define

$$\mathcal{T} \left(\hat{O}_1(z_1) \cdots \hat{O}_n(z_n) \right) = \sum_P (\pm)^P \theta(z_{P(1)}, \dots, z_{P(n)}) \hat{O}_{P(1)}(z_{P(1)}) \cdots \hat{O}_{P(n)}(z_{P(n)})$$

where $\theta(z_1, \dots, z_n)$ is defined as

$$\theta(z_1, \dots, z_n) = \begin{cases} 1 & z_1 > z_2 > \cdots > z_n \\ 0 & \text{otherwise} \end{cases}$$

we have

$$\mathcal{T} \left(\hat{O}_1(z_1) \cdots \hat{O}_n(z_n) \right) = (\pm)^P \mathcal{T} \left(\hat{O}_{P(1)}(z_{P(1)}) \cdots \hat{O}_{P(n)}(z_{P(n)}) \right)$$

The plus sign is for Bosonic operator, and the minus sign is for Fermionic operator. Hamiltonian is treated as Bosonic operator.

- In other words, we have:

$$\frac{d}{dz_1} \mathcal{T} \left(\hat{O}_1(z_1) \hat{O}_2(z_2) \right) = \delta(z_1, z_2) \left[\hat{O}_1(z_1), \hat{O}_2(z_2) \right]_{\mp} + \mathcal{T} \left(\left(\frac{d}{dz_1} \hat{O}_1(z_1) \right) \hat{O}_2(z_2) \right)$$

- For M equal time operators, it acts like a bosonic/fermionic operator under \mathcal{T} , for M being even/odd.
- For n operators, we have:

$$\begin{aligned} \frac{d}{dz_k} \mathcal{T} \left(\hat{O}_1(z_1) \cdots \hat{O}_n(z_n) \right) &= \mathcal{T} \left(\hat{O}_1(z_1) \cdots \hat{O}_{k-1}(z_{k-1}) \left(\frac{d}{dz_k} \hat{O}_k(z_k) \right) \hat{O}_{k+1}(z_{k+1}) \cdots \hat{O}_n(z_n) \right) \\ &\quad + \sum_P (\pm)^P \left(\frac{d}{dz_k} \theta(z_{P(1)}, \dots, z_{P(n)}) \right) \hat{O}_{P(1)}(z_{P(1)}) \cdots \hat{O}_{P(n)}(z_{P(n)}) \end{aligned}$$

- Now we dedicate to calculate the second term. When moving z_k along the contour, only of when it passes along another z_l , will create a term like $\delta(z_k - z_l)$ in the derivative. Consider z_l is the term closest to z_k , there is nothing between them. We have:

- if $l > k$,

$$\begin{aligned} \mathcal{T} \left(\hat{O}_1 \cdots \hat{O}_n \right) &= (\pm)^{l-k-1} \mathcal{T} \left(\hat{O}_1 \cdots \hat{O}_k \hat{O}_l \hat{O}_{k+1} \cdots \hat{O}_{l-1} \hat{O}_{l+1} \cdots \hat{O}_n \right) \\ &= (\pm)^{l-k-1} (\pm)^Q \left(\theta(z_k - z_l) \hat{O}_{Q(1)} \cdots \hat{O}_k \hat{O}_l \hat{O}_{Q(n)} \pm \theta(z_l - z_k) \hat{O}_{Q(1)} \cdots \hat{O}_l \hat{O}_k \hat{O}_{Q(n)} \right) \end{aligned}$$

We see the above second term of the derivative in this case becomes:

$$\begin{aligned} &(\pm)^{l-k-1} (\pm)^Q \left(\delta(z_k - z_l) \hat{O}_{Q(1)} \cdots \left[\hat{O}_k, \hat{O}_l \right]_{\mp} \hat{O}_{Q(n)} \right) \\ &= (\pm)^{l-k-1} \delta(z_k, z_l) \mathcal{T} \left(\hat{O}_1 \cdots \left[\hat{O}_k, \hat{O}_l \right]_{\mp} \hat{O}_{k+1} \cdots \hat{O}_{l-1} \hat{O}_{l+1} \cdots \hat{O}_n \right) \end{aligned}$$

- if $k > l$, similarly we have the derivative as

$$(\pm)^{k-l} \delta(z_k, z_l) \mathcal{T} \left(\hat{O}_1 \cdots \hat{O}_{l-1} \hat{O}_{l+1} \cdots \left[\hat{O}_k, \hat{O}_l \right]_{\mp} \hat{O}_{k+1} \cdots \hat{O}_n \right)$$

- Put them together, we have

$$\begin{aligned} &\sum_{l=k+1}^n (\pm)^{l-k-1} \delta(z_k, z_l) \mathcal{T} \left(\hat{O}_1 \cdots \left[\hat{O}_k, \hat{O}_l \right]_{\mp} \hat{O}_{k+1} \cdots \hat{O}_{l-1} \hat{O}_{l+1} \cdots \hat{O}_n \right) \\ &+ \sum_{l=1}^{k-1} (\pm)^{k-l} \delta(z_k, z_l) \mathcal{T} \left(\hat{O}_1 \cdots \hat{O}_{l-1} \hat{O}_{l+1} \cdots \left[\hat{O}_k, \hat{O}_l \right]_{\mp} \hat{O}_{k+1} \cdots \hat{O}_n \right) \end{aligned}$$

- We will be working with field operators, which has a nice property that the (anti)commutator is a scalar function. Therefore the above formalism could be simplified further:

$$\begin{aligned} &\sum_{l=k+1}^n (\pm)^{l-k-1} \delta(z_k, z_l) \left[\hat{O}_k, \hat{O}_l \right]_{\mp} \mathcal{T} \left(\hat{O}_1 \cdots \tilde{\hat{O}}_k \cdots \tilde{\hat{O}}_l \cdots \hat{O}_n \right) \\ &+ \sum_{l=1}^{k-1} (\pm)^{k-l} \delta(z_k, z_l) \left[\hat{O}_k, \hat{O}_l \right]_{\mp} \mathcal{T} \left(\hat{O}_1 \cdots \tilde{\hat{O}}_l \cdots \tilde{\hat{O}}_k \cdots \hat{O}_n \right) \end{aligned}$$

where $\tilde{\hat{O}}_k$ means exclude this term from the multiplication.

- In order to deal with the field operators, we introduce the following notation:

$$i = \mathbf{x}_i, z_i, \quad j = \mathbf{x}_j, z_j, \dots$$

$$\delta(j; k) = \delta(z_j, z_k) \delta(\mathbf{x}_j - \mathbf{x}_k)$$

- As an example, we have

$$\begin{aligned} \frac{d}{dz_2} \mathcal{T} \left\{ \hat{\psi}_H(1) \hat{\psi}_H(2) \hat{\psi}_H^\dagger(3) \hat{\psi}_H^\dagger(4) \right\} &= \mathcal{T} \left\{ \hat{\psi}_H(1) \left(\frac{d}{dz_2} \hat{\psi}_H(2) \right) \hat{\psi}_H^\dagger(3) \hat{\psi}_H^\dagger(4) \right\} \\ &+ \delta(2; 3) \mathcal{T} \left\{ \hat{\psi}_H(1) \hat{\psi}_H^\dagger(4) \right\} \pm \delta(2; 4) \mathcal{T} \left\{ \hat{\psi}_H(1) \hat{\psi}_H^\dagger(3) \right\} \end{aligned}$$

- We are specifically interested in the following correlators:

$$\hat{G}_n(1, \dots, n; 1', \dots, n') = \frac{1}{i^n} \mathcal{T} \left(\hat{\psi}_H(1) \dots \hat{\psi}_H(n) \hat{\psi}_H^\dagger(n') \dots \hat{\psi}_H^\dagger(1') \right)$$

For $n = 0$, $\hat{G}_0 = \mathbf{1}$

- Therefore we have:

$$\begin{aligned} i \frac{d}{dz_k} \hat{G}_n(1, \dots, n; 1', \dots, n') &= \frac{1}{i^n} \mathcal{T} \left(\hat{\psi}_H(1) \dots \left(i \frac{d}{dz_k} \hat{\psi}_H(k) \right) \dots \hat{\psi}_H(n) \hat{\psi}_H^\dagger(n') \dots \hat{\psi}_H^\dagger(1') \right) \\ &+ \sum_{j=1}^n (\pm)^{k+j} \delta(k; j') \hat{G}_{n-1}(1, \dots, \tilde{k}, \dots, n; 1', \dots, \tilde{j}', \dots, n') \end{aligned}$$

Similarly:

$$\begin{aligned} -i \frac{d}{dz'_k} \hat{G}_n(1, \dots, n; 1', \dots, n') &= \frac{1}{i^n} \mathcal{T} \left(\hat{\psi}_H(1) \dots \left(-i \frac{d}{dz'_k} \hat{\psi}_H(k) \right) \dots \hat{\psi}_H(n) \hat{\psi}_H^\dagger(n') \dots \hat{\psi}_H^\dagger(1') \right) \\ &+ \sum_{j=1}^n (\pm)^{k+j} \delta(j; k') \hat{G}_{n-1}(1, \dots, \tilde{j}, \dots, n; 1', \dots, \tilde{k}', \dots, n') \end{aligned}$$

- Recall the equation of motion for field operators:

$$\begin{aligned} i \frac{d}{dz_k} \hat{\psi}_H(k) &= \hat{h}(k) \hat{\psi}_H(k) + \int d\bar{l} v(k, \bar{l}) \hat{\psi}_H^\dagger(\bar{l}) \hat{\psi}_H(\bar{l}) \hat{\psi}_H(k) \\ -i \frac{d}{dz'_k} \hat{\psi}_H^\dagger(k') &= \hat{\psi}_H^\dagger(k') \hat{h}(k') + \int d\bar{l} v(k', \bar{l}) \hat{\psi}_H^\dagger(k') \hat{\psi}_H^\dagger(\bar{l}) \hat{\psi}_H(\bar{l}) \end{aligned}$$

- If we insert the derivative of field operator back into the derivative of \hat{G}_n , we have something like \hat{G}_{n+1} . Note that: In order to ensure $\hat{\psi}_H^\dagger(1)$ is in front of $\hat{\psi}_H(1)$, we can introduce $1+$:

$$\mathcal{T} \left(\dots \hat{n}_H(\bar{l}) \hat{\psi}_H(k) \dots \right) = \mathcal{T} \left(\dots \hat{\psi}_H^\dagger(\bar{l}^+) \hat{\psi}_H(\bar{l}) \hat{\psi}_H(k) \dots \right) = \pm \mathcal{T} \left(\dots \hat{\psi}_H(k) \hat{\psi}_H(\bar{l}) \hat{\psi}_H^\dagger(\bar{l}^+) \dots \right)$$

Then we have:

$$\begin{aligned} &\frac{1}{i^n} \mathcal{T} \left\{ \hat{\psi}_H(1) \dots \left(i \frac{d}{dz_k} \hat{\psi}_H(k) \right) \dots \hat{\psi}_H(n) \hat{\psi}_H^\dagger(n') \dots \hat{\psi}_H^\dagger(1') \right\} \\ &= h(k) \hat{G}_n(1, \dots, n; 1', \dots, n') \pm \frac{1}{i^n} \int d\bar{l} v(k; \bar{l}) \mathcal{T} \left\{ \hat{\psi}_H(1) \dots \hat{\psi}_H(n) \hat{\psi}_H(\bar{l}) \hat{\psi}_H^\dagger(\bar{l}^+) \hat{\psi}_H^\dagger(n') \dots \hat{\psi}_H^\dagger(1') \right\} \\ &= h(k) \hat{G}_n(1, \dots, n; 1', \dots, n') \pm i \int d\bar{l} v(k; \bar{l}) \hat{G}_{n+1}(1, \dots, n, \bar{l}; 1, \dots, n', \bar{l}^+) \end{aligned}$$

Therefore we have:

$$\begin{aligned} & \left[i \frac{d}{dz_k} - h(k) \right] \hat{G}_n(1, \dots, n; 1', \dots, n') \\ &= \pm i \int d\bar{1} v(k; \bar{1}) \hat{G}_{n+1}(1, \dots, n, \bar{1}; 1', \dots, n', \bar{1}^+) + \sum_{j=1}^n (\pm)^{k+j} \delta(k; j') \hat{G}_{n-1}(1, \dots, \tilde{k} \dots, n; 1', \dots, \tilde{j}' \dots, n') \end{aligned}$$

Similarly, we have:

$$\begin{aligned} & \hat{G}_n(1, \dots, n; 1', \dots, n') \left[-i \frac{\overleftarrow{d}}{dz'_k} - h(k') \right] \\ &= \pm i \int d\bar{1} v(k'; \bar{1}) \hat{G}_{n+1}(1, \dots, n, \bar{1}^-; 1', \dots, n', \bar{1}) + \sum_{j=1}^n (\pm)^{k+j} \delta(j; k') \hat{G}_{n-1}(1, \dots, \tilde{j} \dots, n; 1', \dots, \tilde{k}' \dots, n') \end{aligned}$$

7 Martin-Schwinger hierarchy

- The n -particle Green's function G_n , is defined using \hat{G}_n :

$$\begin{aligned} G_n(1, \dots, n; 1', \dots, n') &= \frac{\text{Tr} \left(e^{-\beta H^M} \hat{G}_n(1, \dots, n; 1', \dots, n') \right)}{\text{Tr} \left(e^{-\beta H^M} \right)} \\ &= \frac{1}{i^n} \frac{\text{Tr} \left(\mathcal{T} \left(e^{-i \int_{\gamma} d\bar{z} \hat{H}(\bar{z})} \hat{\psi}(1) \dots \hat{\psi}(n) \psi^\dagger(n') \dots \psi^\dagger(1') \right) \right)}{\text{Tr} \left(\mathcal{T} \left(e^{-i \int_{\gamma} d\bar{z} \hat{H}(\bar{z})} \right) \right)} \end{aligned}$$

This requires derivation!

- For G_1 , by choosing $z_1 = z$, $z'_1 = z^+$, we have the time dependent ensemble average for $\hat{\psi}^\dagger(\mathbf{x}'_1) \hat{\psi}(\mathbf{x}_1)$, which could be used to calculate the ensemble average of any one-body operator. For example, the density operator:

$$n(\mathbf{x}, z) = \frac{\text{Tr} \left(e^{-\beta H^M} \hat{\psi}_H^\dagger(\mathbf{x}, z) \hat{\psi}_H(\mathbf{x}, z) \right)}{\text{Tr} \left(e^{-\beta H^M} \right)} = \pm i G_1(\mathbf{x}, z; \mathbf{x}, z^+)$$

and the current density operator:

$$\begin{aligned} \mathbf{j}(\mathbf{x}, z) &= \frac{1}{2m i} \frac{\text{Tr} \left(e^{-\beta H^M} \left(\hat{\psi}_H^\dagger(\mathbf{x}, z) \left(\nabla \hat{\psi}_H(\mathbf{x}, z) \right) - \left(\nabla \hat{\psi}_H^\dagger(\mathbf{x}, z) \right) \hat{\psi}_H(\mathbf{x}, z) \right) \right)}{\text{Tr} \left(e^{-\beta H^M} \right)} \\ &= \pm \frac{\nabla - \nabla'}{2m} G_1(\mathbf{x}, z; \mathbf{x}', z^+) |_{\mathbf{x}=\mathbf{x}'} \end{aligned}$$

For G_n it's similar. For example, the interaction energy is:

$$E_{\text{int}}(z) = -\frac{1}{2} \int d\mathbf{x} d\mathbf{x}' v(\mathbf{x}, \mathbf{x}', z) G_2(\mathbf{x}', z, \mathbf{x}, z; \mathbf{x}', z^+, \mathbf{x}, z^+)$$

- We have the differential equation for G_n :

$$\left[i \frac{d}{dz_k} - h(k) \right] G_n(1, \dots, n; 1', \dots, n') \\ = \pm i \int d\bar{1} v(k; \bar{1}) G_{n+1}(1, \dots, n, \bar{1}; 1', \dots, n', \bar{1}^+) + \sum_{j=1}^n (\pm)^{k+j} \delta(k; j') G_{n-1}(1, \dots, \tilde{k} \dots, n; 1', \dots, \tilde{j}' \dots, n')$$

and

$$G_n(1, \dots, n; 1', \dots, n') \left[-i \frac{\overleftarrow{d}}{dz'_k} - h(k') \right] \\ = \pm i \int d\bar{1} v(k'; \bar{1}) G_{n+1}(1, \dots, n, \bar{1}^-; 1', \dots, n', \bar{1}) + \sum_{j=1}^n (\pm)^{k+j} \delta(j; k') G_{n-1}(1, \dots, \tilde{j} \dots, n; 1', \dots, \tilde{k}' \dots, n')$$

This is called the Martin-Schwinger hierarchy.

- We also have the following boundary condition for Green's function:

$$G_n(1, \dots, \mathbf{x}_k, z_i, \dots, n; 1', \dots, n') = \pm G_n(1, \dots, \mathbf{x}_k, z_f, \dots, n; 1', \dots, n')$$

$$G_n(1, \dots, n; 1' \dots, \mathbf{x}'_k, z_i, \dots, n') = \pm G_n(1, \dots, n; 1' \dots, \mathbf{x}'_k, z_f, \dots, n')$$

This is called the Kubo-Martin-Schwinger(KMS) relations.

We'll now discuss an example of the truncation of hierarchy, i.e. the approximation of Green's function.

- For $G(1, 1')$, we have:

$$\left(i \frac{d}{dz_1} - h(1) \right) G(1; 1') = \delta(1; 1') \pm i \int d2 v(1, 2) G_2(1, 2; 1', 2^+) \\ G(1; 1') \left(-i \frac{\overleftarrow{d}}{dz_1} - h(1') \right) = \delta(1; 1') \pm i \int d2 v(1', 2) G_2(1, 2^-; 1', 2)$$

- For $G_2(1, 2; 1', 2')$, we have:

$$\left(i \frac{d}{dz_1} - h(1) \right) G_2(1, 2; 1', 2') = \delta(1; 1') G(2, 2') \pm \delta(1; 2') G(2; 1') \pm i \int d3 v(1, 3) G_3(1, 2, 3; 1', 2', 3^+) \\ \left(i \frac{d}{dz_2} - h(2) \right) G_2(1, 2; 1', 2') = \pm \delta(2; 1') G(1, 2') + \delta(2; 2') G(1; 1') \pm i \int d3 v(2, 3) G_3(1, 2, 3; 1', 2', 3^+) \\ G_2(1, 2; 1', 2') \left(-i \frac{\overleftarrow{d}}{dz_1} - h(1') \right) = \delta(1; 1') G(2, 2') \pm \delta(2; 1') G(1; 2') \pm i \int d3 v(1', 3) G_3(1, 2, 3^-; 1', 2', 3) \\ G_2(1, 2; 1', 2') \left(-i \frac{\overleftarrow{d}}{dz_2} - h(2') \right) = \pm \delta(1; 2') G(2, 1') + \delta(2; 2') G(1; 1') \pm i \int d3 v(2', 3) G_3(1, 2, 3^-; 1', 2', 3)$$

- This inspires us to write $G_2(1, 2; 1', 2')$ into the following formulation:

$$G_2(1, 2; 1', 2') = G(1; 1')G(2; 2') \pm G(1; 2')G(2; 1') + \Upsilon(1, 2; 1', 2')$$

$\Upsilon(1, 2; 1', 2')$ is called the correlation function. For $v = 0$, we can verify that $G_2(1, 2; 1', 2') = G(1; 1')G(2; 2') \pm G(1; 2')G(2; 1')$ satisfy the exact differential equation for G_2 .

- The formulation

$$G_2(1, 2; 1', 2') = G(1; 1')G(2; 2') \pm G(1; 2')G(2; 1')$$

is called the Hartree-Fock approximation. If we insert it back to the differential equation for $G(1; 1')$, we have:

$$\begin{aligned} \left(i \frac{d}{dz_1} - h(1) \right) G(1; 1') &= \delta(1; 1') \pm i \int d2v(1, 2) (G(1; 1')G(2; 2^+) \pm G(1; 2^+)G(2; 1')) \\ G(1; 1') \left(-i \frac{\overleftarrow{d}}{dz_1} - h(1') \right) &= \delta(1; 1') \pm i \int d2v(1', 2) (G(1; 1')G(2^-; 2) \pm G(1; 2')G(2^-; 1')) \end{aligned}$$

- If we define Σ as:

$$\Sigma(1, 2) = \delta(1; 2)V_H(1) + iv(1; 2)G(1; 2^+)$$

where

$$V_H(1) = \pm i \int d3v(1; 3)G(3, 3^+) = \int d\mathbf{x}_3 v(\mathbf{x}_1, \mathbf{x}_3, z_1)n(\mathbf{x}_3, z_1)$$

is the well-known Hartree potential. Then we have

$$\begin{aligned} \left(i \frac{d}{dz_1} - h(1) \right) G(1; 1') &= \delta(1; 1') + i \int d2\Sigma(1, 2)G(2; 1') \\ G(1; 1') \left(-i \frac{\overleftarrow{d}}{dz_1} - h(1') \right) &= \delta(1; 1') + i \int d2G(1; 2)\Sigma(2; 1') \end{aligned}$$

This is the self-consistent equation.

- Now we discuss the derivation of Dyson's equation. Using integral by part and KMS boundary condition, we have:

$$\begin{aligned} &\int d1G_0(2; 1) \left[i \frac{d}{dz_1} - h(1) \right] G(1; 1') \\ &= \int d1G_0(2; 1) \left[-i \frac{\overleftarrow{d}}{dz_1} - h(1) \right] G(1; 1') + i \int d\mathbf{x}_1 G_0(2; \mathbf{x}_1, z_1) G(\mathbf{x}_1, z_1; 1') \Big|_{z_1=z_1}^{z_1=z_t} \\ &= \int d1\delta(2; 1)G(1; 1') = G(2, 1') \end{aligned}$$

With this we can do integral on the self-consistent equation for $G(1; 1')$, and we have:

$$G(1; 2) = G_0(1; 2) + \int d3d4G_0(1; 3)\Sigma(3; 4)G(4; 2)$$

Similarly, we can also get:

$$G(1; 2) = G_0(1; 2) + \int d3d4G(1; 3)\Sigma(3; 4)G_0(4; 2)$$

Dyson's equation is also correct for the general case, not only for the Hartree-Fock approximation here.

We also can discuss the approximation beyond Hartree-Fock.

- For

$$G_2(1, 2; 1', 2') = G(1; 1')G(2; 2') \pm G(1; 2')G(2; 1') + \Upsilon(1, 2; 1', 2')$$

with

$$\left(i \frac{d}{dz_1} - h(1)\right) G(1; 1') = \delta(1; 1') \pm i \int d^2v(1, 2) G_2(1, 2; 1', 2^+)$$

$$\left(i \frac{d}{dz_1} - h(1)\right) G(1; 2') = \delta(1; 2') \pm i \int d^2v(1, 2) G_2(1, 2; 2', 2^+)$$

$$\left(i \frac{d}{dz_1} - h(1)\right) G_2(1, 2; 1', 2') = \delta(1; 1')G(2; 2') \pm \delta(1; 2')G(2; 1') \pm i \int d^3v(1, 3) G_3(1, 2, 3; 1', 2', 3^+)$$

- Therefore we have

$$\begin{aligned} & \left(i \frac{d}{dz_1} - h(1)\right) \Upsilon(1, 2; 1', 2') \\ &= \pm i \int d^3v(1, 3) (G_3(1, 2, 3; 1', 2', 3^+) - G_2(1, 3; 1', 3^+)G(2; 2') \mp G_2(1, 3; 2', 3^+)G(2; 1')) \end{aligned}$$

- Because

$$\begin{aligned} \left[i \frac{d}{dz_2} - h(2)\right] G_3(1, 2, 3; 1', 2', 3') &= \pm \delta(2; 1') G_2(1, 3; 2, 3') + \delta(2; 2') G_2(1, 3; 1', 3') \\ &\pm \delta(2; 3') G_2(1, 3; 1', 2') \pm i \int d^4v(2, 4) G_4(1, 2, 3, 4; 1', 2', 3', 4^+) \end{aligned}$$

- Therefore

$$\begin{aligned} & \left[i \frac{d}{dz_1} - h(1)\right] \left[i \frac{d}{dz_2} - h(2)\right] \Upsilon(1, 2; 1', 2') = i v(1; 2) G_2(1, 2; 1', 2') \\ & - \int d^4v(1; 3) v(2; 4) [G_4(1, 2, 3, 4; 1', 2', 3^+, 4^+) - G_2(1, 3; 1', 3^+) G_2(2, 4; 2', 4^+) \\ & \mp G_2(1, 3; 2', 3^+) G_2(2, 4; 1', 4^+)] . \end{aligned}$$

- If we neglect the higher order term, we have:

$$\left[i \frac{d}{dz_1} - h(1)\right] \left[i \frac{d}{dz_2} - h(2)\right] \Upsilon(1, 2; 1', 2') = i v(1; 2) G_2(1, 2; 1', 2')$$

Therefore

$$\Upsilon(1, 2; 1', 2') = i \int d^3d^4 G_0(1; 3) G_0(2; 4) v(3; 4) G_2(3, 4; 1', 2')$$

8 Exact solution of Martin-Schwinger's Hierarchy from Wick's theorem

- We'll first deal with the non-interacting case $G_{0,n}$, where $v = 0$. We have the following result:

$$G_{0,n}(1, \dots, n; 1', \dots, n') = \left| \begin{array}{ccc} G_0(1; 1') & \dots & G_0(1; n') \\ \vdots & & \vdots \\ G_0(n; 1') & \dots & G_0(n; n') \end{array} \right|_{\pm}$$

This follows from Martin-Schwinger hierarchy if $v = 0$. This is the so-called Wick's theorem.

- This inspires us to calculate G_n in a brute-force way. From the definition, we have:

$$G_n = \frac{1}{i^n} \frac{\text{Tr} \left[\mathcal{T} \left\{ e^{-i \int_{\gamma} d\bar{z} \hat{H}_0(\bar{z})} e^{-i \int_{\gamma} d\bar{z} \hat{H}_{\text{int}}(\bar{z})} \hat{\psi}(1) \dots \hat{\psi}^{\dagger}(1') \right\} \right]}{\text{Tr} \left[\mathcal{T} \left\{ e^{-i \int_{\gamma} d\bar{z} \hat{H}_0(\bar{z})} e^{-i \int_{\gamma} d\bar{z} \hat{H}_{\text{int}}(\bar{z})} \right\} \right]}$$

where \hat{H}_0 and \hat{H}_{int} are respectively one-body and two-body terms for the Hamiltonian.

- If we introduce the notation:

$$\text{Tr} \left[\mathcal{T} \left\{ e^{-i \int_{\gamma} d\bar{z} \hat{H}_0(\bar{z})} \dots \right\} \right] = \langle \mathcal{T} \{ \dots \} \rangle_0$$

which could be physically interpreted as taking average over the non-interacting system. Then our interacting Green's function G_n , using Taylor's expansion, is

$$G_n = \frac{1}{i^n} \frac{\sum_{k=0}^{\infty} \frac{(-i)^k}{k!} \int_{\gamma} d\bar{z}_1 \dots d\bar{z}_k \left\langle \mathcal{T} \left\{ \hat{H}_{\text{int}}(\bar{z}_1) \dots \hat{H}_{\text{int}}(\bar{z}_k) \hat{\psi}(1) \dots \hat{\psi}^{\dagger}(1') \right\} \right\rangle_0}{\sum_{k=0}^{\infty} \frac{(-i)^k}{k!} \int_{\gamma} d\bar{z}_1 \dots d\bar{z}_k \left\langle \mathcal{T} \left\{ \hat{H}_{\text{int}}(\bar{z}_1) \dots \hat{H}_{\text{int}}(\bar{z}_k) \right\} \right\rangle_0}$$

where \hat{H}_{int} is

$$\hat{H}_{\text{int}}(z) = \frac{1}{2} \int dz' \int d\mathbf{x} d\mathbf{x}' v(\mathbf{x}, z; \mathbf{x}', z') \hat{\psi}^{\dagger}(\mathbf{x}, z^+) \hat{\psi}^{\dagger}(\mathbf{x}', z^+) \hat{\psi}(\mathbf{x}', z') \hat{\psi}(\mathbf{x}, z)$$

where

$$v(\mathbf{x}, z; \mathbf{x}', z') = \delta(z, z') \begin{cases} v(\mathbf{x}, \mathbf{x}', t) & \text{if } z = t_{\pm} \text{ is on the horizontal branches of } \gamma \\ v^{\text{M}}(\mathbf{x}, \mathbf{x}') & \text{if } z \text{ is on the vertical track of } \gamma \end{cases}$$

- Now we look at the case of one-particle Green's function. Let $a = (\mathbf{x}_a, z_a), b = (\mathbf{x}_b, z_b)$, we have

$$G(a; b) = \frac{1}{i} \frac{\sum_{k=0}^{\infty} \frac{(-i)^k}{k!} \int_{\gamma} dz_1 \dots dz_k \left\langle \mathcal{T} \left\{ \hat{H}_{\text{int}}(z_1) \dots \hat{H}_{\text{int}}(z_k) \hat{\psi}(a) \hat{\psi}^{\dagger}(b) \right\} \right\rangle_0}{\sum_{k=0}^{\infty} \frac{(-i)^k}{k!} \int_{\gamma} dz_1 \dots dz_k \left\langle \mathcal{T} \left\{ \hat{H}_{\text{int}}(z_1) \dots \hat{H}_{\text{int}}(z_k) \right\} \right\rangle_0}$$

The numerator could be rewritten as

$$\sum_{k=0}^{\infty} \frac{1}{k!} \left(-\frac{i}{2} \right)^k \int d1 \dots dk d1' \dots dk' v(1; 1') \dots v(k; k') \\ \times \left\langle \mathcal{T} \left\{ \hat{\psi}^{\dagger}(1^+) \hat{\psi}^{\dagger}(1'^+) \hat{\psi}(1') \hat{\psi}(1) \dots \hat{\psi}^{\dagger}(k^+) \hat{\psi}^{\dagger}(k'^+) \hat{\psi}(k') \hat{\psi}(k) \hat{\psi}(a) \hat{\psi}^{\dagger}(b) \right\} \right\rangle_0$$

The quantity inside time-ordering operator could be rewritten as

$$\left\langle \mathcal{T} \left\{ \hat{\psi}(a) \hat{\psi}(1) \hat{\psi}(1') \dots \hat{\psi}(k) \hat{\psi}(k') \hat{\psi}^\dagger(k^+) \hat{\psi}^\dagger(k'^+) \dots \hat{\psi}^\dagger(1'^+) \hat{\psi}^\dagger(1^+) \hat{\psi}^\dagger(b) \right\} \right\rangle_0$$

which is exactly

$$i^{2k+1} Z_0 G_{0,2k+1}(a, 1, 1', \dots, k, k'; b, 1^+, 1'^+, \dots, k^+, k'^+)$$

Similarly, the k -th order term of the denominator is

$$i^{2k} Z_0 G_{0,2k}(1, 1', \dots, k, k'; 1^+, 1'^+, \dots, k^+, k'^+)$$

Therefore we have

$$G(a; b) = \frac{\sum_{k=0}^{\infty} \frac{1}{k!} \left(\frac{i}{2}\right)^k \int v(1; 1') \dots v(k; k') G_{0,2k+1}(a, 1, 1', \dots, b, 1^+, 1'^+, \dots)}{\sum_{k=0}^{\infty} \frac{1}{k!} \left(\frac{i}{2}\right)^k \int v(1; 1') \dots v(k; k') G_{0,2k}(1, 1', \dots, 1^+, 1'^+, \dots)}$$

which could be further written using Wick's theorem

$$G(a, b) = \frac{\sum_{k=0}^{\infty} \frac{1}{k!} \left(\frac{i}{2}\right)^k \int v(1; 1') \dots v(k; k') \begin{vmatrix} G_0(a; b) & G_0(a; 1^+) & \dots & G_0(a; k'^+) \\ G_0(1; b) & G_0(1; 1^+) & \dots & G_0(1; k'^+) \\ \vdots & \vdots & \ddots & \vdots \\ G_0(k'; b) & G_0(k'; 1^+) & \dots & G_0(k'; k'^+) \end{vmatrix}_{\pm}}{\sum_{k=0}^{\infty} \frac{1}{k!} \left(\frac{i}{2}\right)^k \int v(1; 1') \dots v(k; k') \begin{vmatrix} G_0(1; 1^+) & G_0(1; 1'^+) & \dots & G_0(1; k'^+) \\ G_0(1'; 1^+) & G_0(1'; 1'^+) & \dots & G_0(1'; k'^+) \\ \vdots & \vdots & \ddots & \vdots \\ G_0(k'; 1^+) & G_0(k'; 1'^+) & \dots & G_0(k'; k'^+) \end{vmatrix}_{\pm}}$$

where the integrals are over $1, 1', \dots, k, k'$.

- Similarly, we have

$$G_2(a, b; c, d) = \frac{\sum_{k=0}^{\infty} \frac{1}{k!} \left(\frac{i}{2}\right)^k \int v(1; 1') \dots v(k; k') \begin{vmatrix} G_0(a; c) & G_0(a; d) & \dots & G_0(a; k'^+) \\ G_0(b; c) & G_0(b; d) & \dots & G_0(b; k'^+) \\ \vdots & \vdots & \ddots & \vdots \\ G_0(k'; c) & G_0(k'; d) & \dots & G_0(k'; k'^+) \end{vmatrix}_{\pm}}{\sum_{k=0}^{\infty} \frac{1}{k!} \left(\frac{i}{2}\right)^k \int v(1; 1') \dots v(k; k') \begin{vmatrix} G_0(1; 1^+) & G_0(1; 1'^+) & \dots & G_0(1; k'^+) \\ G_0(1'; 1^+) & G_0(1'; 1'^+) & \dots & G_0(1'; k'^+) \\ \vdots & \vdots & \ddots & \vdots \\ G_0(k'; 1^+) & G_0(k'; 1'^+) & \dots & G_0(k'; k'^+) \end{vmatrix}_{\pm}}$$

We also have Z/Z_0 , which is just the denominator above

$$\frac{Z}{Z_0} = \sum_{k=0}^{\infty} \frac{1}{k!} \left(\frac{i}{2}\right)^k \int v(1; 1') \dots v(k; k') \begin{vmatrix} G_0(1; 1^+) & G_0(1; 1'^+) & \dots & G_0(1; k'^+) \\ G_0(1'; 1^+) & G_0(1'; 1'^+) & \dots & G_0(1'; k'^+) \\ \vdots & \vdots & \ddots & \vdots \\ G_0(k'; 1^+) & G_0(k'; 1'^+) & \dots & G_0(k'; k'^+) \end{vmatrix}_{\pm}$$

This is the full mathematical description of many body perturbation theory.

9 Analytic continuity rules

Here we consider the analytic property of two-point correlators $k(z, z')$, such as one-particle Green's function.

$$k(z, z') = \text{Tr} [\hat{\rho} \hat{k}(z, z')] = \text{Tr} [\hat{\rho} \mathcal{T} \{ \hat{O}_1(z) \hat{O}_2(z') \}]$$

and the discussion here based on $\hat{O}(t_+) = \hat{O}(t_-)$. We only consider the contour as being the right side of figure 2.

- We have

$$k(z, z') = \theta(z, z') k^>(z, z') + \theta(z', z) k^<(z, z')$$

where $k^>$ and $k^<$ are:

$$k^>(z, z') = \text{Tr} [\hat{\rho} \hat{O}_1(z) \hat{O}_2(z')], \quad k^<(z, z') = \pm \text{Tr} [\hat{\rho} \hat{O}_2(z') \hat{O}_1(z)]$$

- $k(z, z')$ is the same value for z, z' being on forward/backward branch:

$$k^{\lessgtr}(t_+, z') = k^{\lessgtr}(t_-, z'), \quad k^{\lessgtr}(z, t'_+) = k^{\lessgtr}(z, t'_-)$$

- A function is said to belong to Keldysh space, if

$$k(z, z') = k^\delta(z) \delta(z, z') + \theta(z, z') k^>(z, z') + \theta(z', z) k^<(z, z')$$

Here $k^\delta(t) = k^\delta(t_-) = k^\delta(t_+)$.

- On the real time axis, we can define the greater and lesser Keldysh components as followed:

$$\begin{aligned} k^>(t, t') &\equiv k(t_+, t'_-) \\ k^<(t, t') &\equiv k(t_-, t'_+) \end{aligned}$$

- We also define the left and right Keldysh components from $k(z, z')$ with one real time t and one imaginary time $t_0 - i\tau$:

$$\begin{aligned} k^\top(\tau, t) &\equiv k(t_0 - i\tau, t_\pm) \\ k^\perp(t, \tau) &\equiv k(t_\pm, t_0 - i\tau) \end{aligned}$$

- We can also define the Matsubara component $k^M(\tau, \tau')$ with both contour arguments on the vertical track:

$$\begin{aligned} k^M(\tau, \tau') &\equiv k(t_0 - i\tau, t_0 - i\tau') \\ &= \delta(t_0 - i\tau, t_0 - i\tau') k^\delta(t_0 - i\tau) + k_r^M(\tau, \tau') \end{aligned}$$

where

$$k_r^M(\tau, \tau') = \theta(\tau - \tau') k^>(t_0 - i\tau, t_0 - i\tau') + \theta(\tau' - \tau) k^<(t_0 - i\tau, t_0 - i\tau')$$

Because $\delta(t_0 - i\tau, t_0 - i\tau') = i\delta(\tau - \tau')$, therefore

$$k^M(\tau, \tau') = i\delta(\tau - \tau') k^\delta(\tau) + k_r^M(\tau, \tau')$$

- We also define the retarded and advanced component:

$$k^R(t, t') \equiv k^\delta(t) \delta(t - t') + \theta(t - t') [k^>(t, t') - k^<(t, t')]$$

$$k^A(t, t') \equiv k^\delta(t) \delta(t - t') - \theta(t' - t) [k^>(t, t') - k^<(t, t')]$$

and the time-ordered and anti time-ordered component:

$$k^T(t, t') \equiv k(t_-, t'_-) = k^\delta(t) \delta(t - t') + \theta(t - t') k^>(t, t') + \theta(t' - t) k^<(t, t')$$

$$k^{\bar{T}}(t, t') \equiv k(t_+, t'_+) = -k^\delta(t) \delta(t - t') + \theta(t' - t) k^>(t, t') + \theta(t - t') k^<(t, t')$$

There are a lot to be filled in this section.....

10 Physics of one-particle Green's function

We begin by discussing some other formalism of Green's function.

- The Green's function could be regarded as a first quantization operator:

$$\hat{\mathcal{G}}(z_1, z_2) = \int d\mathbf{x}_1 d\mathbf{x}_2 |\mathbf{x}_1\rangle G(1; 2) \langle \mathbf{x}_2|$$

whose matrix element is

$$\langle \mathbf{x}_1 | \hat{\mathcal{G}}(z_1, z_2) | \mathbf{x}_2 \rangle = G(1; 2)$$

- On the other hand, recall that

$$\hat{\psi}(\mathbf{x}) = \sum_i \varphi_i(\mathbf{x}) \hat{d}_i, \quad \hat{\psi}^\dagger(\mathbf{x}) = \sum_i \varphi_i^*(\mathbf{x}) \hat{d}_i^\dagger$$

we can also define the following matrix Green's function:

$$G_{ji}(z_1, z_2) = \frac{1}{i} \frac{\text{Tr} \left[e^{-\beta \hat{H}^M} \mathcal{T} \left\{ \hat{d}_{j,H}(z_1) \hat{d}_{i,H}^\dagger(z_2) \right\} \right]}{\text{Tr} \left[e^{-\beta \hat{H}^M} \right]}$$

- Their relations are:

$$G(1; 2) = \sum_{ji} \varphi_j(\mathbf{x}_1) G_{ji}(z_1, z_2) \varphi_i^*(\mathbf{x}_2) = \sum_{ji} \langle \mathbf{x}_1 | j \rangle G_{ji}(z_1, z_2) \langle i | \mathbf{x}_2 \rangle$$

$$\hat{\mathcal{G}}(z_1, z_2) = \sum_{ji} |j\rangle G_{ji}(z_1, z_2) \langle i|$$

- For non-interacting Green's function, we have:

$$\left(i \frac{d}{dz_1} - \hat{h}(z_1) \right) \hat{\mathcal{G}}_0(z_1, z_2) = \delta(z_1, z_2)$$

For interacting case, we have

$$\left[i \frac{d}{dz_1} - \hat{h}(z_1) \right] \hat{\mathcal{G}}(z_1, z_2) - \int_\gamma d\bar{z} \hat{\Sigma}(z_1, \bar{z}) \hat{\mathcal{G}}(\bar{z}, z_2) = \delta(z_1, z_2)$$

Now we talk about Matsubara Green's function.

- Let $z_1 = t_0 - i\tau_1$ and $z_2 = t_0 - i\tau_2$. The definition of Matsubara Green's function is

$$G_{ji}^M(\tau_1, \tau_2) = \frac{1}{i} \left\{ \theta(\tau_1 - \tau_2) \frac{\text{Tr} \left[e^{(\tau_1 - \tau_2 - \beta)\hat{H}^M} \hat{d}_j e^{(\tau_2 - \tau_1)\hat{H}^M} \hat{d}_i^\dagger \right]}{\text{Tr} \left[e^{-\beta\hat{H}^M} \right]} \pm \theta(\tau_2 - \tau_1) \frac{\text{Tr} \left[e^{(\tau_2 - \tau_1 - \beta)\hat{H}^M} \hat{d}_i^\dagger e^{(\tau_1 - \tau_2)\hat{H}^M} \hat{d}_j \right]}{\text{Tr} \left[e^{-\beta\hat{H}^M} \right]} \right\}$$

Here $\hat{H}^M = \hat{H}(t_0) - \mu\hat{N}$.

- For any one-body operator \hat{O}

$$\hat{O} = \sum_{ij} O_{ij} \hat{d}_i^\dagger \hat{d}_j$$

we have

$$\langle O \rangle = \frac{\text{Tr} \left[e^{-\beta\hat{H}^M} \hat{O} \right]}{\text{Tr} \left[e^{-\beta\hat{H}^M} \right]} = \sum_{ij} O_{ij} \frac{\text{Tr} \left[e^{-\beta\hat{H}^M} \hat{d}_i^\dagger \hat{d}_j \right]}{\text{Tr} \left[e^{-\beta\hat{H}^M} \right]} = \pm i \sum_{ij} O_{ij} G_{ji}^M(\tau, \tau^+)$$

- $G_{ji}^M(\tau_1, \tau_2)$ only depends on $\tau_1 - \tau_2$.

- KMS relation:

$$\hat{\mathcal{G}}^M(0, \tau) = \pm \hat{\mathcal{G}}^M(\beta, \tau), \quad \hat{\mathcal{G}}^M(\tau, 0) = \pm \hat{\mathcal{G}}^M(\tau, \beta)$$

- Therefore the Matsubara Green's function could be expanded using Fourier series:

$$\hat{\mathcal{G}}^M(\tau_1, \tau_2) = \frac{1}{-i\beta} \sum_{m=-\infty}^{\infty} e^{-\omega_m(\tau_1 - \tau_2)} \hat{\mathcal{G}}^M(\omega_m)$$

where the Matsubara frequencies are

$$\omega_m = \begin{cases} \frac{i2m\pi}{\beta} & \text{for bosons} \\ \frac{i(2m+1)\pi}{\beta} & \text{for fermions} \end{cases}$$

- Let's look at example. For

$$\hat{H}^M = \sum_{ij} h_{ij}^M \hat{d}_i^\dagger \hat{d}_j$$

with the equation of motion, we have

$$\left[-\frac{d}{d\tau_1} - \hat{h}^M \right] \hat{\mathcal{G}}^M(\tau_1, \tau_2) = \delta(-i\tau_1 + i\tau_2) = i\delta(\tau_1 - \tau_2)$$

with the help of

$$\delta(\tau) = \frac{1}{\beta} \sum_{m=-\infty}^{\infty} \begin{cases} e^{-i\frac{2m\pi}{\beta}\tau} \\ e^{-i\frac{(2m+1)\pi}{\beta}\tau} \end{cases} = \frac{1}{\beta} \sum_{m=-\infty}^{\infty} e^{-\omega_m\tau}$$

we get

$$\hat{\mathcal{G}}^M(\omega_m) = \frac{1}{\omega_m - \hat{h}^M}$$

Now we discuss lesser/greater Green's function.

- The definition is

$$G_{ji}^<(t, t') = \mp i \frac{\text{Tr} \left[e^{-\beta \hat{H}^M} \hat{d}_{i,H}^\dagger(t') \hat{d}_{j,H}(t) \right]}{\text{Tr} \left[e^{-\beta \hat{H}^M} \right]} = \mp i \sum_k \rho_k \left\langle \Psi_k \left| \hat{d}_{i,H}^\dagger(t') \hat{d}_{j,H}(t) \right| \Psi_k \right\rangle$$

$$G_{ji}^>(t, t') = -i \frac{\text{Tr} \left[e^{-\beta \hat{H}^M} \hat{d}_{j,H}(t) \hat{d}_{i,H}^\dagger(t') \right]}{\text{Tr} \left[e^{-\beta \hat{H}^M} \right]} = -i \sum_k \rho_k \left\langle \Psi_k \left| \hat{d}_{j,H}(t) \hat{d}_{i,H}^\dagger(t') \right| \Psi_k \right\rangle$$

- We have:

$$\left[G_{ji}^>(t, t') \right]^* = -G_{ij}^>(t', t), \quad \left[G_{ji}^<(t, t') \right]^* = -G_{ij}^<(t', t)$$

and consequently

$$\hat{\mathcal{G}}^R(t, t') = \theta(t - t') \left[\hat{\mathcal{G}}^>(t, t') - \hat{\mathcal{G}}^<(t, t') \right] = \left[\hat{\mathcal{G}}^A(t', t) \right]^\dagger$$

- The lesser Green's function could be used to calculate one-body operator. For example:

$$n_i(t) = \pm i \sum_{ij} O_{ij} G_{ji}^<(t, t)$$

- For $t = t_0$, we have for all τ :

$$\hat{\mathcal{G}}(t_0, t_0) = \hat{\mathcal{G}}^M(\tau, \tau^+)$$

- If $\hat{H}(t) = \hat{H}$ for $t > t_0$, we have

$$G_{ji}^<(t, t') = \mp i \sum_k \rho_k \left\langle \Psi_k \left| e^{i\hat{H}(t'-t_0)} \hat{d}_i^\dagger e^{-i\hat{H}(t'-t)} \hat{d}_j e^{-i\hat{H}(t-t_0)} \right| \Psi_k \right\rangle$$

- In general, $G_{ij}^<$ is not a function of $t' - t$, because Ψ_k is not necessarily the eigenstates of driving Hamiltonian \hat{H} .

11 Non-interacting Green's function

We are talking about non-interacting case, where the Hamiltonian is

$$\hat{H}(z) = \sum_{ij} h_{ij}(z) \hat{d}_i^\dagger \hat{d}_j = \sum_{ij} \langle i | \hat{h}(z) | j \rangle \hat{d}_i^\dagger \hat{d}_j$$

- We write $\hat{\mathcal{G}}$ as:

$$\hat{\mathcal{G}}(z_1, z_2) = \hat{\mathcal{U}}_L(z_1) \hat{\mathcal{F}}(z_1, z_2) \hat{\mathcal{U}}_R(z_2)$$

Here $\hat{\mathcal{U}}_{L/R}(z)$ fulfill:

$$i \frac{d}{dz} \hat{\mathcal{U}}_L(z) = \hat{h}(z) \hat{\mathcal{U}}_L(z), \quad i \frac{d}{dz} \hat{\mathcal{U}}_R(z) = -\hat{\mathcal{U}}_R(z) \hat{h}(z)$$

with $\hat{\mathcal{U}}_L(t_{0-}) = \hat{\mathcal{U}}_R(t_{0-}) = \mathbf{1}$.

- The solution of $\hat{\mathcal{U}}_L$ and $\hat{\mathcal{U}}_R$ is

$$\hat{\mathcal{U}}_L(z) = \mathcal{T} \left\{ e^{-i \int_{t_0}^z d\bar{z} \hat{h}(\bar{z})} \right\}, \quad \hat{\mathcal{U}}_R(z) = \overline{\mathcal{T}} \left\{ e^{+i \int_{t_0}^z d\bar{z} \hat{h}(\bar{z})} \right\}$$

- Therefore we have the differential equation for $\hat{\mathcal{F}}$:

$$i \frac{d}{dz_1} \hat{\mathcal{F}}(z_1, z_2) = \delta(z_1, z_2), \quad -i \frac{d}{dz_2} \hat{\mathcal{F}}(z_1, z_2) = \delta(z_1, z_2)$$

- We have

$$\hat{\mathcal{F}}(z_1, z_2) = \theta(z_1, z_2) \hat{\mathcal{F}}^> + \theta(z_2, z_1) \hat{\mathcal{F}}^<$$

where

$$\hat{\mathcal{F}}^> - \hat{\mathcal{F}}^< = -i\hat{\mathbf{1}}$$

- With KMS relations:

$$\hat{\mathcal{G}}(t_{0-}, z') = \pm \hat{\mathcal{G}}(t_0 - i\beta, z') \quad \begin{cases} + \text{ for bosons} \\ - \text{ for fermions} \end{cases}$$

we have

$$\hat{\mathcal{F}}^< = \pm \hat{\mathcal{U}}_L(t_0 - i\beta) \hat{\mathcal{F}}^> = \pm e^{-\beta \hat{h}^M} \hat{\mathcal{F}}^> \quad \begin{cases} + \text{ for bosons} \\ - \text{ for fermions} \end{cases}$$

Then

$$\hat{\mathcal{F}}^< = \mp i \frac{1}{e^{\beta \hat{h}^M} \mp \hat{\mathbf{1}}} = \mp i f(\hat{h}^M)$$

and

$$\hat{\mathcal{F}}^> = \pm i \frac{1}{e^{-\beta \hat{h}^M} \mp \hat{\mathbf{1}}} = -i \bar{f}(\hat{h}^M)$$

where

$$f(\omega) = 1 / [e^{\beta \omega} \mp 1], \quad \bar{f}(\omega) = 1 \pm f(\omega) = e^{\beta \omega} f(\omega)$$

Now we are talking about the Matsubara component:

- Let $z_1 = t_0 - i\tau_1$, $z_2 = t_0 - i\tau_2$, we have

$$\hat{\mathcal{U}}_L(t_0 - i\tau) = e^{-\tau \hat{h}^M}, \quad \hat{\mathcal{U}}_R(t_0 - i\tau) = e^{\tau \hat{h}^M}$$

Then we have

$$\hat{\mathcal{G}}^M(\tau_1, \tau_2) = -i \left[\theta(\tau_1 - \tau_2) \bar{f}(\hat{h}^M) \pm \theta(\tau_2 - \tau_1) f(\hat{h}^M) \right] e^{-(\tau_1 - \tau_2) \hat{h}^M}$$

- Another way to write this, using result from previous section, is that

$$\hat{\mathcal{G}}^M(\tau_1, \tau_2) = \frac{1}{-i\beta} \sum_{m=-\infty}^{\infty} \frac{e^{-\omega_m(\tau_1 - \tau_2)}}{\omega_m - \hat{h}^M}$$

- We can prove they are equivalent.

Now let's talk about lesser and greater component. Inspired by

$$\hat{\mathcal{G}}(z_1, z_2) = -i\hat{\mathcal{U}}_L(z_1) \left(\theta(z_1 - z_2) \bar{f}(\hat{h}^M) \pm \theta(z_2 - z_1) f(\hat{h}^M) \right) \hat{\mathcal{U}}_R(z_2)$$

and with

$$\hat{U}_L(t_{\pm}) = T \left(e^{-i \int_{t_0}^t d\bar{t} \hat{h}(\bar{t})} \right) = \hat{\mathcal{U}}(t), \quad \hat{\mathcal{U}}_R(t_{\pm}) = \hat{\mathcal{U}}^\dagger(t)$$

we have:

- The lesser component:

$$\hat{\mathcal{G}}^<(t_1, t_2) = \mp i \hat{\mathcal{U}}(t_1) f(\hat{h}^M) \hat{\mathcal{U}}^\dagger(t_2)$$

- The greater component:

$$\hat{\mathcal{G}}^>(t_1, t_2) = -i \hat{\mathcal{U}}(t_1) \bar{f}(\hat{h}^M) \hat{\mathcal{U}}^\dagger(t_2)$$

- Furthermore, we have:

$$\begin{aligned} \hat{\mathcal{G}}^<(t_1, t_2) &= \mp i \sum_{\lambda} f(\epsilon_{\lambda}^M) \hat{\mathcal{U}}(t_1) |\lambda^M\rangle \langle \lambda^M| \hat{\mathcal{U}}^\dagger(t_2) \\ &= \mp i \sum_{\lambda} f(\epsilon_{\lambda}^M) |\lambda^M(t_1)\rangle \langle \lambda^M(t_2)| \end{aligned}$$

- The density is

$$n(\mathbf{x}, t) = \pm i G^<(\mathbf{x}, t; \mathbf{x}, t)$$

- If the Hamiltonian is constant, we have

$$\hat{\mathcal{G}}^<(t_1, t_2) = \mp i f(\hat{h}^M) e^{-i\hat{h}(t_1 - t_2)}$$

$$\hat{\mathcal{G}}^>(t_1, t_2) = -i \bar{f}(\hat{h}^M) e^{-i\hat{h}(t_1 - t_2)}$$

There is no dependence on t_0 ! Only dependence on $t_1 - t_2$.

- We can define the Fourier transform:

$$\hat{\mathcal{G}}^<(t_1, t_2) = \int \frac{d\omega}{2\pi} e^{-i\omega(t_1 - t_2)} \hat{\mathcal{G}}^<(\omega)$$

$$\hat{\mathcal{G}}^>(t_1, t_2) = \int \frac{d\omega}{2\pi} e^{-i\omega(t_1 - t_2)} \hat{\mathcal{G}}^>(\omega)$$

We can directly see that

$$\begin{aligned} \hat{\mathcal{G}}^<(\omega) &= \mp 2\pi i f(\hat{h}^M) \delta(\omega - \hat{h}) \\ \hat{\mathcal{G}}^>(\omega) &= -2\pi i \bar{f}(\hat{h}^M) \delta(\omega - \hat{h}) = \pm e^{\beta \hat{h}^M} \hat{\mathcal{G}}^<(\omega) \end{aligned}$$

Now let's discuss other components.

- The retarded Green's function is

$$\begin{aligned} \hat{\mathcal{G}}^R(t_1, t_2) &= \theta(t_1 - t_2) \left(\hat{\mathcal{G}}^>(t_1, t_2) - \hat{\mathcal{G}}^<(t_1, t_2) \right) \\ &= -i\theta(t_1 - t_2) \hat{\mathcal{U}}(t_1) \hat{\mathcal{U}}^\dagger(t_2) = -i\theta(t_1 - t_2) T \left(e^{-i \int_{t_2}^{t_1} d\bar{t} \hat{h}(\bar{t})} \right) \end{aligned}$$

- The advanced Green's function is

$$\hat{\mathcal{G}}^A(t_1, t_2) = i\theta(t_2 - t_1)\bar{T}\left(e^{i\int_{t_2}^{t_1} d\bar{t}\hat{h}(\bar{t})}\right) = \left(\hat{\mathcal{G}}^R(t_2, t_1)\right)^\dagger$$

This doesn't depend on the original density matrix, only depends on the Hamiltonian.

- For constant Hamiltonian $\hat{h}(t) = \hat{h}$, we have

$$\hat{\mathcal{G}}^R(t_1, t_2) = -i\theta(t_1 - t_2)e^{-i\hat{h}(t_1 - t_2)}$$

$$\hat{\mathcal{G}}^A(t_1, t_2) = i\theta(t_2 - t_1)e^{i\hat{h}(t_2 - t_1)}$$

- The Fourier transform is defined as

$$\hat{\mathcal{G}}^{R,A}(t_1, t_2) = \int \frac{d\omega}{2\pi} e^{-i\omega(t_1 - t_2)} \hat{\mathcal{G}}^{R,A}(\omega)$$

- We have the integration form of step function:

$$\theta(t_1 - t_2) = i \int \frac{d\omega}{2\pi} \frac{e^{-i\omega(t_1 - t_2)}}{\omega + i\eta}$$

- Therefore

$$\hat{\mathcal{G}}^R(t_1, t_2) = \int \frac{d\omega}{2\pi} \frac{e^{-i(\omega + \hat{h})(t_1 - t_2)}}{\omega + i\eta}$$

Changing variables from $\omega \rightarrow \omega - \hat{h}$, we have

$$\hat{\mathcal{G}}^R(\omega) = \frac{1}{\omega - \hat{h} + i\eta} = \sum_{\lambda} \frac{|\lambda\rangle\langle\lambda|}{\omega - \epsilon_{\lambda} + i\eta}$$

And because

$$\hat{\mathcal{G}}^A(\omega) = \left[\hat{\mathcal{G}}^R(\omega)\right]^\dagger$$

we have

$$\hat{\mathcal{G}}^A(\omega) = \frac{1}{\omega - \hat{h} - i\eta} = \sum_{\lambda} \frac{|\lambda\rangle\langle\lambda|}{\omega - \epsilon_{\lambda} - i\eta}$$

- Given that

$$\hat{\mathcal{G}}^R - \hat{\mathcal{G}}^A = \hat{\mathcal{G}}^> - \hat{\mathcal{G}}^<$$

we have

$$\hat{\mathcal{G}}^<(\omega) = \pm f\left(\hat{h}^M\right) \left[\hat{\mathcal{G}}^R(\omega) - \hat{\mathcal{G}}^A(\omega)\right]$$

and

$$\hat{\mathcal{G}}^>(\omega) = \bar{f}\left(\hat{h}^M\right) \left[\hat{\mathcal{G}}^R(\omega) - \hat{\mathcal{G}}^A(\omega)\right]$$

- In the case $\hat{h}^M = \hat{h} - \mu$, we have

$$\hat{\mathcal{G}}^<(\omega) = \pm f(\omega - \mu) \left[\hat{\mathcal{G}}^R(\omega) - \hat{\mathcal{G}}^A(\omega)\right], \quad \hat{\mathcal{G}}^>(\omega) = \bar{f}(\omega - \mu) \left[\hat{\mathcal{G}}^R(\omega) - \hat{\mathcal{G}}^A(\omega)\right]$$

- Left and right component:

$$\hat{\mathcal{G}}^{\uparrow}(t, \tau) = \mp i \hat{\mathcal{U}}(t) f(\hat{h}^M) e^{\tau \hat{h}^M} = i \hat{\mathcal{G}}^R(t, t_0) \hat{\mathcal{G}}^M(0, \tau)$$

$$\hat{\mathcal{G}}^{\uparrow}(\tau, t) = -i e^{-\tau \hat{h}^M} \bar{f}(\hat{h}^M) \hat{\mathcal{U}}^{\dagger}(t) = -i \hat{\mathcal{G}}^M(\tau, 0) \hat{\mathcal{G}}^A(t_0, t)$$

- We have time-ordered Green's function

$$\hat{\mathcal{G}}^T(t_1, t_2) = -i \hat{\mathcal{U}}(t_1) \left[\theta(t_1 - t_2) \bar{f}(\hat{h}^M) \pm \theta(t_2 - t_1) f(\hat{h}^M) \right] \hat{\mathcal{U}}^{\dagger}(t_2)$$

and we have

$$\hat{\mathcal{G}}^T(t_1, t_2) = \int \frac{d\omega}{2\pi} e^{-i\omega(t_1 - t_2)} \underbrace{\left[\frac{\bar{f}(\hat{h}^M)}{\omega - \hat{h} + i\eta} \mp \frac{f(\hat{h}^M)}{\omega - \hat{h} - i\eta} \right]}_{\hat{\mathcal{G}}^T(\omega)}$$

- For fermions in zero temperature, $\hat{h}^M = \hat{h} - \epsilon_F$, ϵ_F is the Fermi energy, and we have $f(\epsilon_\lambda - \mu) = \theta(\epsilon_F - \epsilon_\lambda)$. Then we have

$$\hat{\mathcal{G}}^T(\omega) = \sum_{\epsilon_\lambda > \epsilon_F} \frac{|\lambda\rangle\langle\lambda|}{\omega - \epsilon_\lambda + i\eta} + \sum_{\epsilon_\lambda < \epsilon_F} \frac{|\lambda\rangle\langle\lambda|}{\omega - \epsilon_\lambda - i\eta}$$

12 Interacting Green's function

Consider Hamiltonian \hat{H} and corresponding $\hat{H}^M = \hat{H} - \mu \hat{N}$. Consider the eigenstates of $|\Psi_k\rangle$ of \hat{H}^M .

- We have

$$G_{ji}^<(t, t') = \mp i \sum \rho_k \left\langle \Psi_k \left| \hat{d}_i^{\dagger} e^{-i(\hat{H} - E_k)(t' - t)} \hat{d}_j \right| \Psi_k \right\rangle$$

$$G_{ji}^>(t, t') = -i \sum_k \rho_k \left\langle \Psi_k \left| \hat{d}_j e^{-i(\hat{H} - E_k)(t - t')} \hat{d}_i^{\dagger} \right| \Psi_k \right\rangle$$

- Lehmann representation:

$$G_{ji}^<(t, t') = \mp i \sum_{pk} \rho_k \Phi_{pk}^*(i) \Phi_{pk}(j) e^{-i(E_p - E_k)(t' - t)}$$

$$G_{ji}^>(t, t') = -i \sum_{pk} \rho_k \Phi_{kp}(j) \Phi_{kp}^*(i) e^{-i(E_p - E_k)(t - t')}$$

where

$$\Phi_{kp}(i) = \left\langle \Psi_k \left| \hat{d}_i \right| \Psi_p \right\rangle$$

For this term to be nonzero, $|\Psi_p\rangle$ must contain one more particle than $|\Psi_k\rangle$.

- Then we get the Fourier transform:

$$G_{ji}^<(\omega) = \mp 2\pi i \sum_{pk} \rho_k \Phi_{pk}^*(i) \Phi_{pk}(j) \delta(\omega - E_k + E_p)$$

and

$$G_{ji}^>(\omega) = -2\pi i \sum_{pk} \rho_k \Phi_{kp}(j) \Phi_{kp}^*(i) \delta(\omega - E_p + E_k)$$

and we have the property

$$iG_{jj}^>(\omega) \geq 0$$

$$iG_{jj}^<(\omega) \geq 0 \quad \text{for bosons ;} \quad iG_{jj}^<(\omega) \leq 0 \quad \text{for fermions}$$

- For retarded and advanced function, we have

$$\hat{\mathcal{G}}^R(t, t') = i \int \frac{d\omega}{2\pi} \frac{e^{-i\omega(t-t')}}{\omega + i\eta} \int \frac{d\omega'}{2\pi} e^{-i\omega'(t-t')} [\hat{\mathcal{G}}^>(\omega') - \hat{\mathcal{G}}^<(\omega')]$$

therefore

$$\hat{\mathcal{G}}^R(\omega) = i \int \frac{d\omega'}{2\pi} \frac{\hat{\mathcal{G}}^>(\omega') - \hat{\mathcal{G}}^<(\omega')}{\omega - \omega' + i\eta}$$

with

$$\hat{\mathcal{G}}^A(\omega) = [\hat{\mathcal{G}}^R(\omega)]^\dagger$$

then

$$\hat{\mathcal{G}}^A(\omega) = i \int \frac{d\omega'}{2\pi} \frac{\hat{\mathcal{G}}^>(\omega') - \hat{\mathcal{G}}^<(\omega')}{\omega - \omega' - i\eta}$$

therefore

$$G_{ji}^{R/A}(\omega) = \sum_{pk} \frac{\Phi_{kp}(j) \Phi_{kp}^*(i)}{\omega - E_p + E_k \pm i\eta} [\rho_k \mp \rho_p]$$

- For thermodynamic equilibrium,

$$\hat{H}^M = \hat{H} - \mu \hat{N}$$

we have

$$\rho_k = \frac{e^{-\beta(E_k - \mu N_k)}}{\text{Tr} [e^{-\beta(\hat{H} - \mu \hat{N})}]} = e^{-\beta(E_k - E_p) + \beta\mu(N_k - N_p)} \rho_p$$

- We can prove that

$$\hat{\mathcal{G}}^>(\omega) = \pm e^{\beta(\omega - \mu)} \hat{\mathcal{G}}^<(\omega)$$

- We have

$$\hat{\mathcal{G}}^>(\omega) - \hat{\mathcal{G}}^<(\omega) = \hat{\mathcal{G}}^R(\omega) - \hat{\mathcal{G}}^A(\omega)$$

Then

$$\hat{\mathcal{G}}^<(\omega) = \pm f(\omega - \mu) [\hat{\mathcal{G}}^R(\omega) - \hat{\mathcal{G}}^A(\omega)]$$

$$\hat{\mathcal{G}}^>(\omega) = \bar{f}(\omega - \mu) [\hat{\mathcal{G}}^R(\omega) - \hat{\mathcal{G}}^A(\omega)]$$

- For left component, we have

$$\begin{aligned}
G_{ji}^\Gamma(\tau, t') &= -i \sum_k \rho_k \left\langle \Psi_k \left| \underbrace{e^{i(\hat{H}-\mu\hat{N})(-\mathrm{i}\tau)} \hat{d}_j e^{-i(\hat{H}-\mu\hat{N})(-\mathrm{i}\tau)}}_{\hat{d}_{j,H}(t_0-\mathrm{i}\tau)} \underbrace{e^{i\hat{H}(t'-t_0)} \hat{d}_i^\dagger e^{-i\hat{H}(t'-t_0)}}_{\hat{d}_{i,H}^\dagger(t')} \right| \Psi_k \right\rangle \\
&= -ie^{\mu\tau} \sum_k \rho_k \left\langle \Psi_k \left| \hat{d}_j e^{-i(\hat{H}-E_k)(t_0-\mathrm{i}\tau-t')} \hat{d}_i^\dagger \right| \Psi_k \right\rangle
\end{aligned}$$

then

$$\hat{\mathcal{G}}^\Gamma(\tau, t') = e^{\mu\tau} \hat{\mathcal{G}}^>(t_0 - \mathrm{i}\tau, t')$$

Similarly

$$\hat{\mathcal{G}}^\Gamma(t, \tau) = e^{-\mu\tau} \hat{\mathcal{G}}^<(t, t_0 - \mathrm{i}\tau)$$

- For system in thermodynamic equilibrium, we have

$$G_{ji}^M(\tau_1, \tau_2) = \frac{1}{i} \sum_{kn} \rho_p \left[\theta(\tau_1 - \tau_2) e^{\beta(E_p^M - E_k^M)} \pm \theta(\tau_2 - \tau_1) \right] e^{-(\tau_1 - \tau_2)(E_p^M - E_k^M)} \Phi_{kp}(j) \Phi_{kp}^*(i)$$

where

$$E_p^M = E_p - \mu N_p$$

Recall that we proved

$$\frac{1}{-i\beta} \sum_{m=-\infty}^{\infty} \frac{e^{-\omega_m \tau}}{\omega_m - E} = \frac{1}{i} \left[\theta(\tau) e^{\beta E} \pm \theta(-\tau) \right] f(E) e^{-\tau E}$$

Then we have

$$G_{ji}^M(\tau_1, \tau_2) = \frac{1}{-i\beta} \sum_{m=-\infty}^{\infty} e^{-\omega_m(\tau_1 - \tau_2)} \underbrace{\sum_{kp} \frac{\rho_p}{f(E_p^M - E_k^M)} \frac{\Phi_{kp}(j) \Phi_{kp}^*(i)}{\omega_m - E_p^M + E_k^M}}_{G_{ji}^M(\omega_m)}.$$

we have

$$\frac{\rho_p}{f(E_p^M - E_k^M)} = \rho_p \left(e^{\beta(E_p^M - E_k^M)} \mp 1 \right) = \rho_k \mp \rho_p$$

and

$$E_p^M - E_k^M = E_p - E_k - \mu(N_p - N_k) = E_p - E_k - \mu$$

therefore we have

$$G_{ji}^M(\omega_m) = \sum_{kp} \frac{\Phi_{kp}(j) \Phi_{kp}^*(i)}{\omega_m + \mu - E_p + E_k} [\rho_k \mp \rho_p]$$

therefore

$$\hat{\mathcal{G}}^M(\zeta) = \begin{cases} \hat{\mathcal{G}}^R(\zeta + \mu) & \text{for } \text{Im}[\zeta] > 0 \\ \hat{\mathcal{G}}^A(\zeta + \mu) & \text{for } \text{Im}[\zeta] < 0 \end{cases}$$

Thus $\mathcal{G}^M(\zeta)$ is analytic everywhere except along the real axis where it can have poles or branch points.

- As a result,

$$\hat{\mathcal{G}}^M(\omega \pm i\eta) = \hat{\mathcal{G}}^{R/A}(\omega + \mu)$$

which means that \mathcal{G}^M has a discontinuity given by the difference $\mathcal{G}^R - \mathcal{G}^A$ when the complex frequency crosses the real axis.

13 Spectral function

- For systems that are initially in a pure state $\hat{\rho} = |\Psi_{N,0}\rangle\langle\Psi_{N,0}|$, We denote by $|\Psi_{N\pm 1,m}\rangle$ the eigenstates of \hat{H} with $N \pm 1$ particles and define the quasi-particle wavefunctions P_m and the quasi-hole wavefunctions Q_m according to

$$P_m(i) = \langle \Psi_{N,0} | \hat{d}_i | \Psi_{N+1,m} \rangle, \quad Q_m(i) = \langle \Psi_{N-1,m} | \hat{d}_i | \Psi_{N,0} \rangle$$

- Then, the lesser and greater Green's functions become

$$G_{ji}^<(t, t') = \mp i \sum_m Q_m(j) Q_m^*(i) e^{-i(E_{N-1,m} - E_{N,0})(t' - t)}$$

$$G_{ji}^>(t, t') = -i \sum_m P_m(j) P_m^*(i) e^{-i(E_{N+1,m} - E_{N,0})(t - t')}$$

- The Fourier transform of these functions are

$$G_{ji}^<(\omega) = \mp 2\pi i \sum_m Q_m(j) Q_m^*(i) \delta(\omega - [E_{N,0} - E_{N-1,m}])$$

$$G_{ji}^>(\omega) = -2\pi i \sum_m P_m(j) P_m^*(i) \delta(\omega - [E_{N+1,m} - E_{N,0}])$$

$G^<$ is peaked at the removal energies, and $G^>$ is peaked at the addition energies.

- We define

$$\hat{\mathcal{A}}(\omega) = i [\hat{\mathcal{G}}^>(\omega) - \hat{\mathcal{G}}^<(\omega)] = i [\hat{\mathcal{G}}^R(\omega) - \hat{\mathcal{G}}^A(\omega)]$$

- We have

$$A_{jj}(\omega) = 2\pi \left[\sum_m |P_m(j)|^2 \delta(\omega - [E_{N+1,m} - E_{N,0}]) \mp \sum_m |Q_m(j)|^2 \delta(\omega - [E_{N,0} - E_{N-1,m}]) \right]$$

- It is not difficult to verify that:

$$\int \frac{d\omega}{2\pi} A_{ji}(\omega) = \delta_{ji}$$

- We have

$$\hat{\mathcal{G}}^R(\omega) = \int \frac{d\omega'}{2\pi} \frac{\hat{\mathcal{A}}(\omega')}{\omega - \omega' + i\eta}, \quad \hat{\mathcal{G}}^A(\omega) = \int \frac{d\omega'}{2\pi} \frac{\hat{\mathcal{A}}(\omega')}{\omega - \omega' - i\eta}$$

- We have

$$\hat{\mathcal{G}}^<(\omega) = \mp i f(\omega - \mu) \hat{\mathcal{A}}(\omega), \quad \hat{\mathcal{G}}^>(\omega) = -i \bar{f}(\omega - \mu) \hat{\mathcal{A}}(\omega)$$

14 Galitskii–Migdal formula

- For systems of interacting identical particles with Hamiltonian $\hat{H}(t) = \hat{H}_0(t) + \hat{H}_{\text{int}}$, the time-dependent energy $E_S(t_1)$ is considered as the ensemble average of $\hat{H}_S(t_1)$:

$$\hat{H}_S(t_1) \equiv \hat{H}(t_1) - q \int d\mathbf{x}_1 \hat{n}(\mathbf{x}_1) \delta V(1), \quad \delta V(1) = V(\mathbf{r}_1, t_1) - V(\mathbf{r}_1)$$

- Then we have

$$E_S(z_1) = \sum_k \rho_k \langle \Psi_k | \hat{U}(t_{0-}, z_1) \left[\int d\mathbf{x}_1 d\mathbf{x}_2 \hat{\psi}^\dagger(\mathbf{x}_1) \langle \mathbf{x}_1 | \hat{h}_S(z_1) | \mathbf{x}_2 \rangle \hat{\psi}(\mathbf{x}_2) + \frac{1}{2} \int d\mathbf{x}_1 d\mathbf{x}_2 v(\mathbf{x}_1, \mathbf{x}_2) \hat{\psi}^\dagger(\mathbf{x}_1) \hat{\psi}^\dagger(\mathbf{x}_2) \hat{\psi}(\mathbf{x}_2) \hat{\psi}(\mathbf{x}_1) \right] \hat{U}(z_1, t_{0-}) | \Psi_k \rangle$$

$$\text{where } \hat{h}_S(z_1) = \hat{h}(z_1) - q\delta V(\hat{\mathbf{r}}_1, z_1).$$

- In contour formalism, we have

$$E_S(z_1) = \pm i \int d\mathbf{x}_1 d2 h_S(1; 2) G(2; 1^+) - \frac{1}{2} \int d\mathbf{x}_1 d2 v(1; 2) G_2(1, 2; 1^+, 2^+)$$

- Since we have

$$\left[\left(i \frac{d}{dz_1} - i \frac{d}{dz_2} \right) G(1; 2) \right]_{2=1^+} - \int d3 [h(1; 3) G(3; 1^+) + G(1; 3^+) h(3; 1)] = \pm 2i \int d3 v(1; 3) G_2(1, 3; 1^+, 3^+)$$

- Then, we have

$$E_S(z_1) = \pm i \int d\mathbf{x}_1 \left\langle \mathbf{x}_1 \left| \left[\hat{h}_S(z_1) - \frac{1}{2} \hat{h}(z_1) \right] \hat{\mathcal{G}}(z_1, z_1^+) \right| \mathbf{x}_1 \right\rangle \pm \frac{i}{4} \int d\mathbf{x}_1 \left[\left(i \frac{d}{dz_1} - i \frac{d}{dz_2} \right) \left\langle \mathbf{x}_1 \left| \hat{\mathcal{G}}(z_1, z_2) \right| \mathbf{x}_1 \right\rangle \right]_{z_2=z_1^+}$$

- For $z_1 = t_0 - i\tau_1$, $h_S(z_1) = h(z_1) = h^M$, then the initial energy E_S^M is

$$E_S^M = \pm \frac{i}{2} \frac{1}{-i\beta} \sum_m e^{\eta\omega_m} \int d\mathbf{x} \left\langle \mathbf{x} \left| (\omega_m + \hat{h}^M) \hat{\mathcal{G}}^M(\omega_m) \right| \mathbf{x} \right\rangle$$

- For $z_1 = t_{\pm}$, we have $\hat{h}_S(t) = \hat{h}(t) - q\delta V(\hat{\mathbf{r}}, t)$, then

$$E_S(t) = \pm \frac{i}{4} \int d\mathbf{x} \left\langle \mathbf{x} \left| \left(i \frac{d}{dt} - i \frac{d}{dt'} + 2\hat{h}(t) \right) \hat{\mathcal{G}}^<(t, t') \right| \mathbf{x} \right\rangle \Big|_{t'=t} - q \int d\mathbf{x} n(\mathbf{x}, t) \delta V(\mathbf{r}, t)$$

- If $\hat{H}(t) = \hat{H}$, then

$$E_S = \pm \frac{i}{2} \int \frac{d\omega}{2\pi} \int d\mathbf{x} \left\langle \mathbf{x} \left| (\omega + \hat{h}) \hat{\mathcal{G}}^<(\omega) \right| \mathbf{x} \right\rangle$$

This is called the Galitskii–Migdal formula.

- For noninteracting system, the above formula becomes

$$E_S = \sum_{\lambda} f(\epsilon_{\lambda}^M) \epsilon_{\lambda}$$
